**COMORIN, CAPE**, a headland in Madras state forming the southernmost point of India. It is in latitude 8° 4' 20" N., longitude 77° 35' 35" E., at the southern end of the Cardamon hills, themselves a continuation of the Western Ghats. At the apex of the headland is Comorin village, with the temple of Kanya Kumari, the "virgin" (an attribute of the goddess Devi). This is a much-frequented place of pilgrimage which has been famous at least since the beginning of the Christian era (when it was so described by the author of the *Periplus*). (L. D. S.)

**COMORO ISLANDS** (FRENCH TERRITOIRE DES COMORES), a group of volcanic islands at the northern end of the Mozambique channel, lie roughly halfway between the Malagasy Republic (Madagascar) and the African mainland in latitude 11° to 13° S. After 1947 the islands were an overseas territory of France. Pop. (1958) 181,288. Area 832 sq.mi.

**Physical Geography.**—From southeast to northwest the islands are: (1) Mayotte (144 sq.mi.), which has a basalt plateau rising to 2,165 ft. and a coastal plain on the west. Mayotte is partly encircled by an irregular coral reef, within which are the islets of M'Zambourou and Pamanzi. On Pamanzi is Dzaoudzi, the capital of the group. Opposite it on the main island is the port of M'Sapéré. (2) Anjouan (164 sq.mi.) is a triangular island rising centrally in a volcanic massif (M'Tingui) reaching 5,177 ft. Mutsamudu on the northwest coast is its chief town. Pomoni on the south coast is an anchorage formerly used by British warships for coaling. (3) Mohéli (81 sq.mi.), the smallest of the group, is a basalt plateau about 1,000 ft. high, ending in the west in an escarped ridge reaching 2,592 ft. Its chief towns are Fomboni on the north coast and Nioumachoua in the southwest. (4) Grande Comore (443 sq.mi.), the largest and loftiest island, rises near its southern end in the dome-shaped active volcano of Kartala (7,746 ft.). In the north many truncated conical volcanic peaks rise from a plateau of about 2,000 ft. In the southwest is Moroni (pop. [1958] 6,448) and on the north coast the town of Mitsamiouli.

**Climate.**—The tropical climate has two clearly marked seasons: a fresh, dry period between May and October and a hot, humid season between November and April. In November the onset of the monsoon (*cassasi*) brings the highest temperatures (Dzaoudzi, average minimum in December, 82° F.). The highest rainfall occurs in January (11–15 in.) and the summer also bring cyclones, often accompanied by waterspouts and damaging tidal waves. During the winter the temperature falls with the southeast trade wind (*coussi*), reaching a minimum in July (Dzaoudzi, 73° F.). The annual rainfall varies between 39 and 118 in.

The hydrology of the islands is of importance, especially on arid Grande Comore. Rain sinks so deeply into the lavas and porous rocks that wells (*foumbous*) deep enough to reach the water table can be sunk only in the coastal lowlands, where the water obtained is brackish. Hence most of the supplies for Grande Comore and Dzaoudzi are drawn from reservoirs filled in the rainy season. In the other islands it is possible for streams to form

on the decomposite basalt lavas and wells can be sunk.

**Vegetation and Animal Life.**—The character of the vegetation varies with height and degree of exposure to the wind. Only about 16% of the land remains covered with the primitive forest. A coastal zone of mangroves is followed by one of coconut palms, mangoes and bananas up to about 1,300 ft., above which the forest zone (mahogany, rosewood, tcamahac) rises to about 5,900 ft. On the highest peaks only broom, heather and lichens grow. The animal life is allied to that of Malagasy rather than to the mainland of Africa; it includes some land birds and a lemur peculiar to the islands. Turtles abound along the coasts and are exported. In the 1950s a number of specimens of the primeval coelacanth (*q.v.*) were caught in the surrounding waters.

**History.**—The Comoro Islands were shown on Diogo Ribero's world map of 1527 but the first European to visit them appears to have been the British mariner James Lancaster about 1591. The dominant influence and civilization in the islands was then and for long afterward Arab. In 1843 France took possession of Mayotte and in 1886 the sultans of the other three islands were placed under French protection. In 1914 the group was subordinated to the governor general of Madagascar and in 1925 was given its own local administration; in 1947 it became an overseas territory of France. In a referendum held in 1958 the Comoro Islands voted to retain overseas territory status. In 1960 they were granted internal autonomy.

**People.**—The people are of diverse origins. Malay immigrants and Arab traders have mixed with Sakalavas and other Malagasy tribes and with various African peoples brought in as slaves. The most important community are the Antalaotra, who are of mixed origin and are most numerous in Anjouan (hence their incorrect name Anjouanais) and Grande Comore. Most of the people are Shafi'i Muslims living in single-story whitewashed stone houses surmounted by a terrace for prayer. They converse mainly in Arabic; Swahili, the language used for commerce, has been transcribed into Arabic characters. In the late 1950s there were in the islands 35 elementary schools with more than 2,500 pupils, 1 secondary and 1 technical school. Of the population, about half live on Grande Comore and about one-third on Anjouan. There are about 1,000 Europeans.

**Economy.**—The lack of pasture and of flat cultivable land calls for a large importation of foodstuffs. Subsistence agriculture on small plots shaded by coconut palms or fruit trees and tilled on a family basis yields cassava, sweet potatoes and other vegetables; some mountain rice is grown. There are about 25,000 goats and about 10,000 cattle. European plantations dating from the early 19th century first cultivated sugar cane; this was supplanted in the 20th century by vanilla, to which were added perfume plants (ilang-ilang, citronella, bitter orange, basil). Later, coconuts, coffee, cocoa and (in Anjouan and Grande Comore) sisal were cultivated. The plantations, which cover 35% of the total area, are mostly managed by companies which also own trading posts, sawmills and soap and oil factories. There are three hydroelectric power plants.

The plantations, while providing a living for part of the population, do not succeed in balancing the economy, and the value of imports substantially exceeds that of exports. Emigration is extensive, and in 1956 alone about 40,000 persons emigrated to the Majunga province of Malagasy.

Regular shipping services call at the islands, all four of which are linked with Majunga by daily air services. In the 1960s there were about 400 mi. of roads.

See C. Robequain, *Madagascar et les bases dispersées de l'Union Française* (1958); H. Isnard, "L'Archipel des Comores," *Cah. d'Océanographie*, vol. vi, pp. 5 ff. (1953). (J. D.)

**COMPACT, INTERSTATE.** The compact is one of many methods, ranging from informal administrative agreement to judicial settlement, for achieving interstate co-operation and adjustment within the federal system of the United States.

Authority for the states to compact with one another is contained in art. i, sec. 10 of the United States constitution, which provides that "No State shall, without the Consent of Congress, . . . enter into any Agreement or Compact with another State, or

with a foreign Power, . . ." The history of the compact, however, predates the constitution by well over 100 years, and several such agreements were concluded during the colonial period and under the Articles of Confederation, from which the present compact clause was derived.

The compact possesses several distinguishing characteristics. It is a formal contractual agreement between states that takes precedence over ordinary state statute, usually receives congressional consent and is enforceable in the United States supreme court. While the exact wording of the compact clause would indicate that congressional consent must always be obtained, judicial construction has to some extent modified this provision. Beginning with the decision in *Virginia v. Tennessee*, 148 U.S. 593 (1893), the court held that consent may be implied where subsequent acts of congress have recognized action taken under provisions of the compact. In the same decision the court also said that only those agreements that affect the political balance of power within the federal system must have congressional consent.

Prior to the 20th century the interstate compact was used infrequently and for limited purposes such as the determination of boundary lines and criminal jurisdiction over boundary waters. In 1921 creation of the Port of New York authority established by compact the first joint administrative agency of a continuing nature. One year later the Colorado River compact, which provides for allocation of waters among the upper and lower basin states, marked the first use of a compact to meet common problems on a regional basis. It also marked the beginning of a series of water allocation compacts in the western states. With the formation of the Interstate Compact to Conserve Oil and Gas in the mid-1930s, which provided for membership of all oil-producing states, the use of the compact transcended the regional level. The Interstate Compact for the Supervision of Parolees and Probationers, also drafted in the 1930s, sought and finally achieved the co-operation of all the states in a joint administrative operation. After that time the compact device was used increasingly on a regional and national basis to provide interstate co-operation in a variety of fields including conservation, control and use of natural resources, provision of welfare and correctional facilities, education, law enforcement, mental health and civil defense.

**COMPAGNI, DINO** (c. 1257-1324), Italian historiographer of the value of whose work owes much to his personal experience of politics, was born in Florence of a substantial family of the *popolo* (see FLORENCE). Well educated, he was enrolled as a master in the silk merchants' guild in 1280 and rose to be one of the priors of the *signoria* (1289), gonfalonier of justice (1293) and prior again (1301). In 1301, however, the Black Guelphs, with the help of Pope Boniface VIII and Charles of Valois, overthrew the White Guelph faction to which Dino belonged. He then withdrew from public affairs.

Dino's *Cronica delle cose occorrenti ne' tempi suoi* is valuable for its detailed analysis of the events between 1280 and 1312 in which he and Dante lived and for its revelation of the author's character—a loyal citizen and a devout Christian. First published by L. Muratori (1726), it was edited by I. del Lungo, *Dino Compagni e la sua Cronica*, 3 vol. (1879-87; Eng. trans., *The Chronicle of Dino Compagni*, 1906). The authorship of an allegorical poem in Provençal, *L'intelligenza* (ed. by V. Mistruzzi, 1928), generally ascribed to Dino, is sometimes contested.

**COMPANY**, the name given in the United Kingdom to incorporated groups of persons; i.e., a number of persons considered as a legal entity or fictitious person with property, powers and liabilities separate from those of its members. In British usage the term denotes the historic chartered companies of the 17th century as well as the modern industrial and commercial organizations. In the United States the latter are commonly called corporations, a term that is used in Great Britain chiefly to refer to noncommercial organizations. (See CORPORATION.) The terms company and corporation are often loosely used interchangeably

This article will trace the economic and legal development of the modern limited-liability company which carries on its business for the purpose of profit in England. For further discussions of specialized types of company see BANKING; CHARTERED COMPANY; INSURANCE; FRATERNAL ORGANIZATION; PARTNERSHIP; and SAVINGS AND LOAN ASSOCIATION.

### HISTORY

**Medieval Period Until 1500.**—The concept of incorporation has been of the greatest importance in the development of trade and industry. The idea of the *persona ficta*, taken over from Roman law by the canon law, was accepted by the common law at first in connection with ecclesiastical bodies and later with other bodies of which the boroughs and guilds were the most important. By the 15th century the common law classified corporations into the corporation sole (ecclesiastical offices such as bishop or vicar but also including the crown) and the corporation aggregate (incorporation of a group of persons). Incorporation generally required a grant from the crown under the royal prerogative, but it was accepted in this period that incorporation could also be conferred by statute. Control was thus kept over various associations of persons which might threaten the state's power. Although there was little legislation on the subject, certain fundamental characteristics of incorporations began to emerge from case law. A corporation is a person in law distinct from its members, and it holds its own property distinct from theirs. The individual property of members cannot be taken to pay the debts of the corporation and vice versa. In matters of conveyance and contract the corporation is bound only if its seal is affixed, except in matters of small importance. There was, however, little tendency to work out logical deductions from these principles and further development was slow. It depended more on expediency than on principle and had little connection with the early forms of commercial association—the guild (*q.v.*) and the medieval contract of partnership.

The guild was a close association of members of a trade bound together for purposes of mutual aid and protection, the benefits of the associate being often enhanced by trading rights and privileges granted by the state. Sometimes the guild would undertake a joint transaction but usually this was left to individual members who might be grouped together in trading partnership. The trading communities of the middle ages spread from Italy and produced two forms of such partnerships. One, the *commenda*, was an early form of limited partnership, in which a financier lent capital to his active partner, his liability being limited by the amount of such capital. This form did not take root in Britain although it flourished on the continent and later its example became an important argument in the struggle for limited liability. In its earliest days, the *commenda* was regarded as a purely temporary arrangement for trading purposes. The *societas* was a more permanent association, linked by the same idea of brotherhood that permeated the guilds, and English law soon established the principle of the unlimited liability of each partner to creditors. Such a form of association is suitable only for a small number of active partners but, owing to the difficulties in obtaining incorporation, this form later became the basis upon which lawyers provided, with the help of the peculiarly English doctrine of the trust, an unsatisfactory although workable approximation to incorporation.

The earlier form of chartered company, the regulated company, developed from the trade guild. It dealt mainly with overseas trade and its members traded on their own account. The *societas* not only influenced the later form of the regulated company, the incorporated joint-stock company, but also formed the basis for the unincorporated joint-stock company.

**1500–1720.**—The great growth of the chartered company, incorporated by royal charter for the regulation and development of foreign trade, took place in the 16th century. Permission to incorporate depended on government policy, including questions of regal revenues, and trading monopolies and privileges. At first each member traded with his own stock and such associations were known as regulated companies, but later a common or joint

stock was formed in which members had transferable shares. In the later part of this period, due to difficulties in obtaining a charter (especially for internal trade), unincorporated joint-stock companies were also created. These could be formed only on the basis of an enlarged partnership, despite its legal defects. Commerce and industry became established upon a capitalist basis, with a banking and credit system and a market in shares and stock. The wealthier classes, seeking to invest their capital, came into association with merchants and entrepreneurs. The foundation of the Bank of England in 1694 was of great importance, for it was carried out on the joint-stock principle. The individual loans from financiers to the government were changed into the joint stock of the new bank on the incorporation of the lenders. The bank held government securities upon which it could create credit.

By the end of the 17th century enough joint-stock companies had been formed to give rise to the specialized trade of stockbroking. The boom years of 1692–95 were followed by a slump in 1696, when the government intervened to regulate the brokers and check gambling. Despite this warning, promotion of companies, trafficking in charters and speculation in shares increased, revealing the fact that the law was incapable of stopping rash or even fraudulent promotions. Such uncontrolled speculation culminated in the speculative boom of 1719–20 and the disaster of the South Sea Bubble (*q.v.*). The South Sea company had taken over the national debt of about £31,000,000 and thus established a fund of credit for its grandiose schemes. Although the terms were unfavourable, the government's approval of the scheme (secured by bribery) and the glowing prospects of expansion of trade encouraged a general speculative mania. Panic-stricken, parliament intervened and passed the Bubble act (1720), an exceptionally ill-drafted measure whose most important provisions were never clarified although the act was not repealed until 1825. It purported to make action as a corporate body and the raising of transferable stock illegal, unless with specific legal authority. Acting under obsolete charters was also made illegal, but there was a declaration that nothing should prevent the carrying on of trade in partnership in accordance with the current law. Immediately ensuing prosecutions under the act and its uncertain effect brought about a general crisis in which many companies were destroyed.

**1720–1825.**—The result of the crisis was to discredit the unincorporated joint-stock company and until the 19th century official opinion remained hostile to incorporation by charter or statute, except for public services such as banking, canals, water supplies and fire and marine insurance (see PUBLIC UTILITIES). This view found support in a well-known passage in Adam Smith's *Wealth of Nations* (1776). It seems probable that the economic effect was not large although industry must have been deprived of some capital which would otherwise have been available to accelerate the onset of the industrial revolution. Thus, faced with the impossibility of obtaining incorporation by statute or charter, and sheltering under the very uncertainty of the Bubble act, businessmen and lawyers combined to re-establish unincorporated joint-stock companies. Ingenious legal use was made of the trust in combination with partnership, and many joint-stock companies were formed by means of deeds of settlement. Under such a deed the subscribers agreed to be associated in a company with a joint stock divided into transferable shares. The deed appointed trustees in whom the property of the company was vested, and who were authorized to sue for wrongs to such property. In this way some of the procedural difficulties of suing could be avoided. Sometimes the deed provided that members were not to be liable beyond the amount of their shares for the company's debts, although such a provision was almost certainly not valid in law. However, practical immunity from creditors seems to have been secured through the procedural difficulties involved in suing a fluctuating body of members.

Many such companies were founded before 1800, mainly for insurance. After a minor prosecution in 1723 no further actions under the Bubble act were undertaken until 1807 (*R v. Dodd*). The court dismissed the case, on the ground that there had been no major prosecutions for 87 years, but warned that for the future the act could not be ignored; the main question of illegality was

left undecided. From the subsequent confusing litigation it emerged that a limited power of transfer of shares was legal, and the decision whether or not the association was beneficial to the public and outside the mischief of the Bubble act was a question of fact for a jury. Incorporation remained difficult to obtain but by way of compromise an act was passed allowing unincorporated companies to sue and be sued in the name of a principal officer, a privilege expensive to obtain and therefore denied to most companies.

During the boom of 1824 the inadequacies of the law allowed promoters to make quick profits from a gullible public, and the undoubted abuses gave strength to the old arguments against joint-stock enterprise. Parliament repealed the Bubble act in 1825, making no attempt to regulate joint-stock companies and leaving the legality of joint-stock companies as a question for common law. However, pressure of economic demand for the joint-stock form was sufficient to offset the legal doubts and the hostility of the authorities. Formations at this time included 74 mining companies, 29 gas, 20 insurance, 54 canal and railroad, 67 steam navigation, 11 trading, 26 building, 24 provisions and 292 miscellaneous companies.

**1825-1856.**—The slump of 1826 led to the disappearance of most of the companies promoted in 1824. According to one estimate, 624 companies had been formed with a total capital of £372,000,000 of which only 127 survived until 1872; 136 companies formed before 1824 also survived the slump but many of these were canal, gas and insurance companies.

As the industrial revolution gathered momentum, freedom to incorporate with limited liability (subject to suitable safeguards) became even more urgently needed. Official, and even a preponderance of commercial, opinion remained bitterly opposed to reform on the grounds that a sound economy must be based on private enterprise with unlimited liability, except in the case of public utilities, and that joint-stock companies sapped enterprise, tended to monopoly and encouraged rash speculation and fraudulent promotions. Nevertheless the great growth of joint-stock banking between 1826 and 1835 when 60 such banks were founded, and the great railway boom, which was at its height between 1835 and 1837, encouraged more realistic arguments in favour of constructive legislation. Little opposition was offered to the granting of limited liability to the railway companies by private act of parliament and a minor step forward was taken through the Trading Companies act of 1834. This act empowered the crown to confer by letters patent such corporate privileges other than limited liability as could be obtained by charter or by special act. For the first time under a general act registration of members was required.

In 1836 and 1837 the great debate as to limited liability continued with reference to the joint-stock banks and a proposal to amend the law of partnership by introducing limited partnerships. The report made in 1837 to the board of trade on the latter issue advised against the adoption of limited partnerships which were then the general practice on the continent and in the United States. However, parliament amended the act of 1834 by the Chartered Companies act, 1837, making the important addition that letters patent could expressly limit the liability of members to a specified amount per share. If the board of trade had not adopted a very restrictive policy in granting such letters patent (only 50 obtained these privileges between 1837 and 1854), this hybrid and illogical form of quasi-incorporation might have become established as the pattern for commercial companies, thus delaying fundamental reform. As it was, the continuing pressure to form joint-stock companies and in particular some notorious instances of fraudulent insurance companies (satirized by Dickens in *Martin Chuzzlewit* in 1843-44), caused the board of trade to secure the appointment of a parliamentary committee on joint-stock companies in 1841 and Gladstone, who had become president of the board of trade, took over the chairmanship in 1843. The committee thoroughly investigated the regulation of joint-stock companies and recommended, as an antidote to fraudulent promotions, publicity by a system of registration and sound regulations for the constitutions of companies. The Joint-Stock Companies

act (1844) which followed was indeed epoch-making. Incorporation was to be obtained merely by registration, and thus the basis of the modern system was laid. For the first time, a distinction was made between a joint-stock company and the ordinary partnership, by requiring registration of all companies with more than 25 members. Publicity was secured by requiring the filing of particulars prior to the issue of a prospectus and the acceptance of deposits on shares, leading to provisional registration, followed by full registration after the deed of settlement had been registered. The act required half-yearly returns of members to be made. Auditors were to be appointed, and the directors were to cause full and fair balance sheets to be made up and filed with the registrar of companies (whose office was then inaugurated). Existing companies who wished to become incorporated were required to register certain particulars and to amend their deeds of settlement to conform with the act.

In the seven lean years of depression which started in 1837, introducing the social unrest of the hungry '40s, the success of the railways was a noteworthy exception to the general stagnation. However by 1844 funds seeking investment had accumulated, and a new railway boom no doubt contributed to economic recovery in the following years. The railways expanded from less than 2,000 mi. in 1843 to 5,000 mi. in 1849, their capital increasing from £65,000,000 to over £200,000,000. This development stimulated a great number of investors and the growth of local stock exchanges, bringing about what has been called the democratization of the money market. By 1856 nearly 1,000 companies were registered under the act of 1844. Almost half of them were public utilities such as gas and water companies, and shipping and mining were prominent. The list included only 1 woollen and 13 cotton companies, but breweries and food totaled 30. One contemporary estimate reckoned that capital was increasing at the rate of £40,000,000 a year.

The economic expansion increased the agitation for limited liability. The broad principle of laissez-faire, then at its height, was paradoxically invoked to attack the previous arguments based on the virtues of unlimited liability and private enterprise, on the ground that there should be freedom to all to contract on the basis of limited liability. The restrictive policy of the board of trade in granting corporate privileges was heavily criticized, as savouring of monopoly and prerogative. Social reformers, influenced by the revolutionary activities of the 1840s, desired to give the working classes the opportunity of co-operating in joint enterprises and of investing their small savings. Parliamentary committees were set up in 1850 and 1851, and a royal commission was appointed the following year; it proceeded to hold a very wide canvass of current opinion both at home and abroad. Foreign opinion was mainly in favour of limited liability, but in England the opinions of experts were evenly divided and in 1854 the report of the commission, signed by a bare majority, advised against it. The report was heavily and widely criticized. Eventually in 1855, when the country was preoccupied with the Crimean War, the government, possibly sensitive to criticism that it was doing nothing constructive at home, hastily secured the passing of the Limited Liability act, which extended the privilege of limited liability to companies securing registration under the 1844 act, except in insurance and banking. This act was re-enacted as the Joint-Stock Companies act, 1856, whose provisions reflected the current supremacy of the laissez-faire principle. Some of the safeguards in the acts of 1844 and 1855, such as registration of the prospectus and the requirement of minimum paid-up capital, were dropped. Incorporation was to be obtained by the simple registration of the memorandum and articles of association by any seven persons. The word limited (usually abbreviated Ltd.) had to be added to the name of the company. Limited liability was extended to banks in 1858 and to insurance companies in 1862. The limited liability company was thus established and became the most important of all forms of commercial associations.

There was a striking increase in the number of promotions. Between 1856 and 1862, 1,575 companies were registered (excluding abortive and small companies), covering a wide field of activities. Formations included 272 mining, 114 cotton, 30 iron and steel, as

well as shipping, streetcars, household goods, food and provisions, breweries, flour mills, hotels, theatres, newspapers and chemicals.

**1856 Onward.**—The act of 1856 and other acts were consolidated by the Companies act, 1862. Company history since this period may be stated briefly. The board of trade began the practice of appointing committees of experts to review company law at intervals of about 20 years. The main acts passed as a result of these committees are the Companies (Consolidation) act, 1908, the Companies act, 1929, and the Companies act, 1948. This legislation tended to give greater protection to the investing public by tightening statutory requirements regarding company accounts and prospectuses. Here the London stock exchange and the increasingly high standards set by the professional accountancy bodies have had great influence.

Companies may still be incorporated by act of parliament and many private companies were formed this way by private act in the 19th century—the Company Clauses acts, 1845–89, providing a general code of corporate powers and duties for this purpose. Some of these companies remain but others have been transformed under measures of nationalization into public incorporated boards. Building societies and co-operative societies also have their special forms of statutory incorporation. Friendly societies and trade unions have reached quasi-incorporative status. In many ways the law is chaotic, more especially in regard to companies that do not come under the Companies act, 1948. Case-law development has thus been of great importance; and, indeed, some of the fundamental principles are the result of important decisions by the house of lords in the last quarter of the 19th century, including the doctrine of *ultra vires* and the principle of the maintenance of capital. Their lordships' decision in the famous case of *Salomon v. Salomon* in 1897 firmly established the company as a separate legal entity, distinct from its members, and enabled small businesses to take advantage of the act of 1862. Parliament accepted this practice in the Companies act of 1907 when provision was made for registration of private companies with at least two members. Ironically, in the same year the Limited Partnerships act at last permitted a partnership to include partners with limited liability on the continental model, a concession which has been little used owing to the greater attractions of the private company. During the 20th century case law developed continuously, not always with completely acceptable or consistent results.

Company law now forms the legal structure for the major part of the economic and business activities of the country though it is still largely based on the model constructed in 1862. In conclusion, mention must be made of certain wider issues which might lead to substantial modifications of the law and thus of the structure of individual companies. On the assumption that the greater part of industry and commerce would not be taken over by the state but would remain in private hands, it was suggested that company law ought to be extended to cover the responsibility of the company to the employees and the consumer as well as to the shareholders. In the case of the bigger corporate bodies, which are managed in effect by self-perpetuating boards of directors, the legal theory of control by the shareholders is largely illusory; the employees of the company are in more intimate relationship with management than are the shareholders, and in many cases have more to lose. In the early 1960s on the continent of Europe, legislation appeared to be strengthening employee representation. As regards the consumer, tentative steps have been taken since World War II in the form of laws against monopoly and restrictive price controls, culminating in the Restrictive Trade Practices act, 1956, and the establishment of the Restrictive Trade Practices court. These measures do not appear to be as stringent as the antitrust legislation of the United States, which makes monopolistic practices subject to the criminal code. See also MONOPOLY.

## COMPANY LAW

**Types of Company.**—Incorporation may be obtained in three ways: (1) By statute, involving promotion of a private bill in parliament. The use of this method is declining and is beyond the scope of this article. In addition, a public statute may provide for incorporation and this method was widely used in connection with

nationalization. (2) By royal charter or letters patent (by petition to the crown). In practice this is confined to nonprofit-making cases; e.g., a new university might be founded in corporate form by such means. (3) By registration under the Companies act, 1948. In theory 15 different types of company are registrable, but in practice the commonest registrations are companies limited by shares (public and private) for commercial profit-making purposes and guarantee companies (with or without a share capital) for multifarious purposes not involving the making of profit.

A list of incorporated bodies would include local authorities, water boards, universities, building societies, co-operative societies, provident societies, public boards (for nationalized industries and services), as well as the various types of company incorporated under the 1948 act. All of them are distinguished from unincorporated associations, such as partnerships and clubs, by the legal fact of their being separate legal entities having a common seal. This diversity raises numerous problems for the legislature (e.g., of organization and taxation) and for the courts (e.g., interpretation of statute law and questions of criminal and civil liability).

**Companies Under the 1948 Act.**—The basic requirement is the filing of the memorandum and articles of association of the company, together with related documents, with the registrar of companies. On the payment of any fees and duties applicable, the registrar issues a certificate of incorporation which is conclusive evidence of incorporation. Normally the memorandum provides for the constitution of the company, while the articles provide for internal regulation of its affairs. Model clauses for both documents were set out in the Companies act, 1862, and this practice was followed in subsequent acts. The memorandum must state the name of the company and its objects and whether the registered office is in England or Scotland. If the liability of the members is limited by shares or guarantee, this limitation must also be stated, together with the share capital if any.

In practice the objects are widely expressed so as to mitigate the application of the *ultra vires* doctrine, which was developed by the courts after a leading case decided by the house of lords in 1875. Under this principle, any act of the company which is not covered by its objects is null and void and cannot be ratified even by the consent of all members. (The better legal opinion is that this doctrine does not apply to chartered companies.) The effect of the principle was further mitigated by changes in the 1948 act, which make it easier for the objects clause to be altered, but the principle remains as a trap for the unwary. There is no statutory requirement as to the contents of the articles (except as mentioned below for private companies); great variations, therefore, are found. In practice public companies have their own articles, while private companies usually adopt the model form with some special articles of their own. The public generally is deemed to have notice of the contents of the articles as well as of the memorandum, since both are open to public inspection. Changes in the articles can be made by special resolution (defined below).

**Public and Private Companies.**—The formal distinction between public and private companies was first made in the Companies act, 1908. The legislature thus recognized that it was reasonable for individual traders to turn their businesses into companies. Public companies must have at least seven members, but the private company need have only two. Its popularity is clear from the fact that at the end of 1958 private companies numbered 318,800 with paid-up capital of £2,623,000,000, while public companies numbered 10,933 with paid-up capital of £4,608,000,000. A private company must by its articles restrict the right to transfer shares, limit its members to 50 (with exceptions) and prohibit any invitation to the public to subscribe for its shares or debentures. Clearly, therefore, a company which needs to raise capital from the public usually must be a public company, while the private-company form provides the facilities and benefits of incorporation for individual traders and partnership firms.

The legislature granted certain privileges to private companies, the most important perhaps being freedom from having to publish accounts. This privilege tended to be abused when public com-

panies started to form private subsidiary companies, and in the 1948 act private companies were subdivided into exempt private companies which retain the old privileges, and the rest, which do not—the intention being to restrict these privileges to the genuine private business. The 1948 act also defined subsidiary companies and provided for the publication of group accounts. The statutory definition of the exempt private company may be summed up as follows: all shareholders must hold in their own right and not as nominees; no corporation must hold any shares; debenture holders (see *Borrowing*, below) must be limited to 50; there must be no arrangement by which the policy of the company is determined by persons other than its directors, shareholders or debenture holders. Private companies which are so successful as to outgrow the private-company form are easily converted into public companies by altering the articles and complying with the requirements of the 1948 act regarding the filing of a prospectus or statement in lieu mentioned below.

**Promotion and Flotation of Public Companies.**—It is necessary to protect members of the public asked to subscribe for securities in a public company. Two main aspects of such protection may be mentioned.

First, the courts themselves, with little assistance from the legislature, have laid down a standard of duty based on good faith which will apply to anyone who takes steps to form a company, public or private. Such a person is called a promoter. Although not technically a trustee for the company, he is held to be in a fiduciary position toward it and may, for instance, be liable to account for secret profits made by him which have not been disclosed to an independent board of directors of the company. (The man who turns his own business into a private company is a promoter and there will probably be no independent board, but presumably he does not need protection against himself.)

Secondly, in the case of public companies the legislature constantly added to the requirements of the prospectus defined by the 1948 act as meaning "any prospectus, notice, circular, advertisement or other invitation, offering to the public for subscription or purchase any shares or debentures of a company." The 1948 act requires a considerable amount of information to be set out in the prospectus. The emphasis is on protection by publicity and disclosure, and there is no onus on the registrar or any other public authority to check the accuracy of the information. Subscribers, however, are given a statutory right to sue promoters and directors for loss or damage sustained by reason of any untrue statement, and there is also criminal liability for issuing a prospectus containing untrue statements. In addition, in many cases the proposed issue will be subject to scrutiny under stock-exchange regulations; e.g., if it is necessary to obtain stock-exchange permission to deal in the securities offered.

One vital item that has usually to be stated in the prospectus is the minimum subscription. This is the estimate of the directors of the minimum amount required to be raised by the issue to pay for any property to be purchased, to defray preliminary expenses and to provide working capital. While the 1948 act and the decided cases established the principle of maintenance of capital once subscribed (see *Capital*, below), this provision is the only legal requirement tending to ensure that adequate capital is available. The company cannot proceed to carry on business unless it is raised. Usually, not only the minimum subscription but also the whole issue will be covered by underwriting; this is a form of contract under which professional underwriters agree to take up shares not subscribed for in return for a commission which must not exceed 10% of the issue price of the shares or exceed any less percentage stated in the company's articles. The rate of commission, if any, has to be stated in the prospectus and its rate is some indication of the market prospect for the issue. The normal common-law and equitable remedies may also be available to subscribers who suffer loss through a fraudulent or inaccurate prospectus. The Prevention of Fraud (Investments) act, 1958, was mainly designed to protect small investors by preventing share-pushing, but it also has some wide provisions which overlap the prospectus requirements of the 1948 act (e.g., it prohibits written invitations to buy or sell a company's securities unless made by a

member of a recognized stock exchange or licensed dealer or unless there is a proper prospectus under the act).

**Capital.**—In a business sense the word capital may be used to refer to the loan capital as well as to the share capital of a company, but in its legal sense it means only the share capital. The 1948 act required that the memorandum shall state the amount of the share capital (usually called the nominal capital) and the division thereof into shares of a fixed amount, and it is common for detailed provisions to be set out in the articles. The usual division is into ordinary shares and preference shares (corresponding to the U.S. distinction between common stock and preferred stock): preference shareholders rank before the ordinary shareholders, being entitled to be paid a limited dividend and to return of capital in a winding-up before dividends are paid or capital returned to the latter. From the accounting and business point of view the capital may be looked upon as the value of the net assets of a company after all its liabilities are discharged. Two important principles of law were laid down to ensure that share capital is actually raised and maintained. First, shares can only be treated as paid up to the extent of the money actually received in cash or in assets equivalent to the value transferred. Secondly, the principle of maintenance of capital was worked out by the courts and the legislature, the two most important rules being that any reduction of capital has to receive the consent of the court and that dividends must not be paid out of capital. Premiums received on shares must be paid to a share-premium account and are for most purposes treated as capital. (See also *Stock*.)

**Rights of Shareholders.**—A person becomes a member of a company either by signing the memorandum or, more commonly, by applying for and being allotted shares, or by taking a transfer of shares from another shareholder. A certificate sealed by the company is issued to him and is prima facie evidence of his title and ownership which the company is normally prevented from denying. The company must also keep a register of members. Shares are usually transferable by a deed of transfer. Share warrants which pass title by mere delivery, although allowed, are not much used in Great Britain. The voting and other rights of shareholders are provided for in the articles, which usually also contain provisions for the variation of rights of different classes of shareholders. The rights of minorities of shareholders receive considerable protection. Case-law decisions have held that a minority may sue in the company's name or in their own names according to the circumstances. There are various provisions in the 1948 act under which minorities can refer matters to the court and, under a new section, the court was given powers to protect oppressed minorities by issuing orders for regulating the conduct of the company's affairs or for the purchase of shares, as an alternative to the drastic power of ordering a winding-up. In addition, the act increased the powers of the board of trade to appoint inspectors to investigate and report on a company's affairs, powers which are very wide and which are available in case of fraud, misfeasance, misconduct and oppression. In addition, a new power was given to investigate the real ownership and control of a company (this was the legislative answer to the criticism of the common practice of nominee shareholdings).

**Direction and Management.**—This is usually vested in a board of directors who need not be shareholders unless the articles require a share qualification, as they usually do. The 1948 act defines director as including any person occupying the position of director by whatever name called. Directors, other than the initial directors, are normally appointed by the company at a general meeting. The articles usually provide for retirement of a proportion of the directors annually, those retiring being eligible for re-election. In order to increase the control of the directorate by the shareholders in a general meeting, the 1948 act provided that a company may, by ordinary resolution (i.e., one passed by a simple majority of votes), remove a director before the expiration of his term of office, despite any other provision in the articles or agreement between the company and the director. A director so removed may have a legal right to compensation or damages for breach-of-service agreement, which may deter shareholders from exercising this power of removal. The articles commonly en-

power the directors to appoint from their ranks a managing director or directors. It is now firmly established by the case law that the board of directors is, for certain purposes, not merely the agent of the company but the company itself. There is thus a division of powers between the general meeting and the board. Except as powers are expressly reserved to the general meeting, they will be exercisable by the board, which is not so much an agent as a primary organ of the company. Where there is a managing director there will be a further division of powers. No doubt the general meeting retains ultimate control, which it exercises by its power to amend the articles or to remove the directors.

Individual directors are agents of the company and not trustees, although they owe fiduciary duties to the company: they must, for instance, act bona fide in what they consider is in the interests of the company as a whole; they must not fetter their discretion as to future acts; nor must they place themselves in positions where their personal interests conflict with their duties to the company. Since the strict application of these rules would vitiate any contract between the company and any of its directors, it became common to relax such rules by special provisions in the articles, and there are statutory provisions regulating the position of directors and making disclosure of personal interest by them necessary. It is also clear that directors must not make secret profits, and difficult questions may arise in the case of offers being made to take over all or any of the shares (take-over bids): a statutory duty compels directors to disclose payments that may have been made to them personally in connection with the transaction. In addition, the total amount of remuneration paid to directors must be included in the annual balance sheet of the company, and a separate register of directors' shareholdings, which is subject to a limited right of inspection by members and debenture holders, must be kept by the company. Directors, as agents of the company, incur no personal liability for proper acts done in good faith but will be liable to the company for acts of misfeasance, including negligence and breach of duty. Any article which exempts a director in this regard is void under the 1948 act; the act, however, empowers the court to grant relief if it appears that he has acted honestly and reasonably and ought, in the circumstances, to be excused. Directors may also incur personal liability to third parties under the principle of breach of warranty of authority in respect of *ultra vires* acts. Directors, like other agents, may also incur criminal liability, and the 1948 act provides for the imposition of penalties upon directors and other officers who fail to comply with certain provisions or who permit their companies to fail to comply.

**General Meetings.**—The ultimate residue of power in a company resides in the general meeting of members of the company. Apart from the meeting required to be held by every public company within three months after it is entitled to commence business, at which time a report on its initial activities is made, the 1948 act requires an annual meeting to be held. The articles usually divide the business transacted into ordinary and special, ordinary business being the declaration of a dividend, the consideration of the accounts or balance sheets, the reports of the directors and auditors, the election of directors and the appointment of and the fixing of the remuneration of the auditors. All other business is special, the general nature of which must be stated in the notice of the meeting. Extraordinary meetings can also be held at any time. These can be called either by the board of directors or by a stated minimum of members under the requisitioning procedure in the 1948 act. The members and the auditor must be given 21 days notice of annual general meetings and of all other meetings at which a special resolution is to be proposed, and 14 days notice of other meetings. The articles may, however, restrict the right of certain classes of shareholders in regard to attendance and voting at meetings.

Three types of resolution are available: ordinary (passed by a simple majority), special and extraordinary (both passed by a three-quarters majority of votes cast). Voting is usually by show of hands in the first instance, but a poll may be demanded by a statutory minimum of members, when voting will usually be on the basis of one vote for each share held. There is also a statutory

right to appoint a proxy or agent (who need not be a member) to attend and vote. A proxy may vote on a poll and join in demanding one. Almost complete control is given to the member or members who hold three-quarters of the voting shares, since this provides power to pass any type of resolution. However, a simple majority of voting shares gives effective control. In the case of large companies with numerous members each holding only a few shares, it is often stated that effective control is obtained by the acquisition of 25% to 40% of the voting shares. The position may be complicated, however, by the issue of nonvoting shares or by weighted voting which may enable control to be exercised by members holding only a small proportion of the company's share capital. The question of control is also basic to the accounting provisions in the 1948 act with respect to holding companies and subsidiaries.

**Accounts and Auditors.**—It was not until 1908 that companies were required to publish their balance sheets. Under the 1948 act every company must keep proper books, as may be necessary to give a true and fair view of the state of the company's affairs and to explain its transactions. The directors must lay before the annual general meeting a profit-and-loss account and balance sheet. The 1948 acts lay down in considerable detail what these accounts shall contain and, for the first time, provides that a controlling company must publish group accounts in which the accounts of its subsidiaries are included. Under the definition in the act, company B will be a subsidiary of company A if A is a member of B and controls the composition of its board of directors or if A holds more than half in nominal value of its equity capital (which will normally be the ordinary capital but would include participating preference capital). The definition appears to leave loopholes for evasion. A subsidiary may be either a public or private company (but cannot be an exempt private company, for reasons stated above).

An auditor of a company must have proper professional qualifications and must not be a director, officer or servant of the company. These provisions are relaxed in the case of the exempt private company.

**Profits and Dividends.**—It is a cardinal rule of company law that dividends can be paid out of profits only and must not be paid out of capital (as this would infringe the principle of maintenance of capital). The case law is complicated. Two points may be stressed here. First, no provision need be made to make good a loss or depreciation of fixed assets (e.g., land, factories, plant, machinery), but losses of circulating assets (e.g., stock-in-trade) in the current accounting period must be made good (although such losses in a previous accounting period can be ignored). Secondly, the courts have constantly stated that the question of what constitute profits is one of fact for businessmen rather than one of law. If the articles allow, it is also possible to pay a dividend out of a capital profit, although this is not usual. The power to declare what dividend shall be paid is usually reserved to the board of directors, which must, of course, take into account the rights of the shareholders under the articles.

**Borrowing.**—Power to borrow is normally included in the objects clause of the memorandum, although it would be implied in the case of a commercial company. The articles often limit the exercise of this power by the board of directors. Money borrowed is commonly called loan capital, but the legal principles applicable are distinct from those concerning share capital; e.g., the interest on loan capital will be a debt due from the company and may, if there are no profits, have to be paid out of capital. The 1948 act allows a loan to be made irredeemable, but otherwise it may be repaid according to its terms without any need for the consent of the court. Loans may either be unsecured or, more commonly, secured on all or some of the assets of the company. The security given by the company is usually called a debenture, a written document which defines the property charged and contains the conditions of the loan. Generally speaking, the form of the document will have to take account of the relevant body of law applicable to the type of asset charged (e.g., real-property law in the case of a fixed charge on land).

The charge known as a floating charge (commonly given by a

debenture) is only possible in the case of companies but not in that of an individual trader or firm. This type of charge, which is not permitted in Scotland, is a charge on the assets of the company generally which permits the company to deal with its assets in the normal course of business until the security is enforced by the lender, whereupon the charge is said to crystallize and attaches to the actual assets then held (subject to any prior charge on such assets). Indeed, one of the advantages of incorporation (e.g., for the small trader) is the greater credit facilities thus made available. When the lenders are numerous, debenture stock is usually issued, sometimes accompanied by a trust deed with trustees in whose favour the charges are created. The prospectus provisions will apply to an invitation to the public to subscribe for debentures. Power is nearly always given to the debenture holders or their trustees to appoint a receiver to seize and realize the assets and repay the money secured, or a receiver can be appointed by the court. In accordance with the policy of publicity, particulars of all charges by a company must be registered within 21 days of their creation with the registrar of companies. If not so registered, any security given will be void against the liquidator and any creditor of the company.

**Liquidation (Winding-Up) and Dissolution.**—A company may be wound up compulsorily by the court or voluntarily; a voluntary winding-up may be, but seldom is, continued under the court's supervision. Of the circumstances in which a company may be wound up compulsorily, the most important is insolvency. The court has a broad jurisdiction in cases where winding-up is just and equitable; e.g., where the substratum of a company has gone, where the company was initiated to carry out a fraud or where a minority is being oppressed. The winding-up proceedings may be initiated by a creditor, a member or the company itself and, when the compulsory winding-up order has been made, a liquidator usually nominated by the creditors is appointed by the court. The liquidator realizes the assets, pays the debts (some of which are, by statute, preferential) and distributes the surplus among the members. He has extensive powers, though in many cases these are subject to the discretion of the court or, in some cases, of a committee of inspection. Voluntary winding-up is the most common, initiated by the company itself by special resolution or, if it is insolvent, by extraordinary resolution. If the company is expected to pay its debts within 12 months, the liquidator is appointed by the members, with whom the control continues for the 12 months, after which control is transferred to the creditors if the debts are still unpaid. In other cases the ultimate decision in choosing the liquidator rests with the creditors, and provision is made for the appointment of a committee of inspection, upon which the members may be represented, to assist the liquidator. The liquidator has much the same powers and duties as in a compulsory winding-up and can, if necessary, obtain the directions of the court.

Dissolution is effected in a compulsory winding-up by a court order and in a voluntary winding-up after the liquidator has laid his final accounts before the members and creditors. A company may also be dissolved without winding-up if it is moribund.

**Reorganization and Amalgamation.**—Reconstruction can be effected by means of a scheme of arrangement with the sanction of the court, under a statutory procedure which enables a three-quarters majority in value of any class of creditors or members present at a meeting convened by the court to bind the whole of the class. Before the court gives its sanction, it must be satisfied regarding the fairness of the scheme. Procedure also exists for a solvent company to reconstruct, by special resolution, into a new company, substituting shares in the new company for shares in the old, such reconstruction being subject to the right of dissenting members to have their interest purchased. These procedures are also available for amalgamation and, in addition, a statutory procedure enables outstanding shares to be acquired by another company where it has already acquired 90% of those shares.

**Nonprofit-Making Companies Under the 1948 Act.**—Incorporation holds many advantages for noncommercial associations and ventures of many kinds. Usually, such bodies will register as guarantee companies without a share capital, a member's

liability being limited to the fixed amount guaranteed by him as stated in the memorandum, which will also provide that all profits shall be used to further the company's objects. Where such a company is formed for promoting commerce, art, science, religion, charity or any other useful object, the board of trade may license it to dispose with the word "limited."

**Overseas Companies.**—Companies incorporated abroad and carrying on business in Great Britain are subject to certain requirements of the 1948 act and must register their constitution and file annual accounts. They must also comply with prospectus provisions similar to those required for native companies.

**Incorporation and Nationalization.**—After 1945 nationalization led to the statutory creation of various public corporations for the control of certain basic industries and public utilities. The boards of management are appointed by a minister of the crown who is responsible to parliament. They may be regarded as an interesting development of company law. A decision of the court of appeal supports the view that they are not servants or agents of the crown, that their employees are not civil servants and that their property is not crown property. They have no shareholders or capital and are not subject to the 1948 act, but their liabilities at common law and under general statute law appear to be the same as those of companies registered under that act. See also references under "Company" in the Index volume.

**COMPANY, CHARTERED:** see CHARTERED COMPANY.  
**COMPANY, MILITARY.** In military organization, the company is the smallest body of troops that functions as a complete administrative unit. Although the term "ship's company" remains in naval usage to designate the officers and crew assigned to a vessel, company is most commonly taken to refer to army units. Two related terms—battery of artillery, troop of cavalry—have been retained in most armies as equivalent to company.

A military company consists of a headquarters for its internal control and administration and two or more platoons organized and equipped to perform the company's operational functions. It is usually commanded by a captain, although in British commonwealth armies majors have sometimes commanded companies. This practice has also spread to other armies as the equipment and technical operations of companies have become more complex. The company headquarters keeps administrative records pertaining to the personnel, equipment and supply of the company. The company commander discharges the basic responsibilities for training, discipline and providing for the welfare of the personnel.

In medieval armies the term company referred loosely to the body of men accompanying a lord or knight into the field. During the 14th century discharged soldiers sometimes formed themselves into "free companies" and plundered at their pleasure. Some free companies were taken into the service of France against Spain; others served as mercenaries in European wars of the next three centuries. One such company was immortalized by Sir Arthur Conan Doyle in his novel *The White Company*.

As the organization of European armies developed, individual companies were brought together in larger tactical formations, and eventually became subdivisions of brigades or regiments. Gustavus Adolphus in 1631 organized the Swedish infantry into 150-man companies, with four companies to a battalion and three battalions to a brigade. French, British and early American infantry regiments usually consisted of ten companies of about 100

men each. Gen. James Wolfe, the hero of Quebec, added elite light-infantry companies to be posted on the flanks of a regiment in battle. As the rifle replaced the musket in the 19th century, infantry companies adopted more dispersed tactical formations and were organized in battalions within the regiment for control.

During World War I all armies experimented with the tactical use of supporting weapons in infantry companies, but such weapons were generally too heavy to be carried by foot soldiers. It was not until World War II, when lighter machine guns, mortars and antitank weapons had been developed, that crew-served weapons became a normal part of the infantry rifle company. In the United States army, the rifle company in 1945 had a strength of 6 officers and 187 men, and was composed of a company headquarters, three rifle platoons of three squads each and a weapons platoon in which were placed light, crew-served weapons for close fire support. Although some modifications in personnel and organic weapons took place after World War II, the basic structure of the rifle company, *i.e.*, headquarters, three (sometimes four) rifle platoons and a supporting weapons platoon, remained basically the same through several U.S. army reorganizations that drastically altered the size, composition and even the names of other types of units. Rifle companies of other nations were similarly organized.

Companies in modern armies vary widely in size and equipment, usually being built around a function or mission (*e.g.*, signal repair, medical ambulance, engineer bridge, reconnaissance, military police companies) or around a weapon or class of weapons (*e.g.*, tank, rifle or infantry, mortar companies). One characteristic all companies have in common, however, is basic administrative unity so that they can be absorbed as required into larger military formations such as the battalion (*q.v.*). (E. Sr.; X.)

**COMPARISON**, or grading, in linguistics, refers to the modification of an element of speech (an adjective or adverb in English) to denote varying degrees of quantity, quality or relation, usually in Indo-European languages, advancing grades; declining grades are indicated by correlatives.

Some languages (*e.g.*, Welsh) have forms for an equative degree ("as good as"), and some have comparisons in nouns (Sanskrit *aśvas* "horse," but *aśvataras* "sort of horse," *i.e.*, "mule"). Historically these forms are strictly intensive, not comparative or superlative. But most frequent are the comparative degree, formed by inflection (for example, "kinder") or other means ("more kind"), intermediate between the positive ("kind") and the superlative ("kindest" or "most kind") degree. Generally speaking, the comparative degree now compares two units and the superlative more than two. As double comparatives such as "lesser" (originally vulgarisms) come to be accepted, the comparative value of the suffix (*e.g.*, *-ter* in Latin *noster* "ours," *i.e.*, "not yours"), which was at first purely relative or relational, may be lost.

In rhetoric, the general term comparison implies that the units being compared have more similarities than differences, or may be classified together. Comparisons in the form of figures of speech (*q.v.*) include metaphors, similes and analogies. In a simile the comparison is made explicit, often with the words "as" or "like," whereas in a metaphor it is implicit. An analogy usually shows the resemblance of two things not in themselves, but in several points of similarity.

See E. Sapir in *Philosophy of Science*, vol. II, pp. 93-116 (1944). (J. Wh.)

**COMPASS**, a term, the evolution of the various meanings of which is obscure; the general sense is "measure" or "measurement," and the word is used thus in various derived meanings—area, boundary, circuit.

It is also more particularly applied to a mathematical instrument (pair of compasses) for measuring or for describing a circle, and to the mariner's compass.

The mariner's compass is an instrument by which the course of a ship can be regulated and by which the direction of landmarks, etc., can be observed. The use of the mariner's compass in slightly differing forms has been extended to aircraft, to land vehicles and to purposes of surveying. Though the actual requirements of each differ, the basic principles remain the same.

Compasses for these purposes fall into three main categories: the magnetic compass, which depends upon the earth's magnetic field to obtain its directive force; the gyrocompass (*q.v.*), which obtains its directive force from the rotation of the earth; and the solar or astrocompass, the use of which depends upon the sun or a star being visible. Some magnetic compasses can be made to drive repeater compasses. If a gyroscope is used in such a system either to stabilize the magnetic element or to smooth out oscillations in the transmission system the arrangement is correctly called a gyromagnetic compass, though it is sometimes described as a gyrocompass.

## HISTORY OF THE MARINER'S COMPASS

The discovery that a loadstone, or a piece of iron which has been touched by a loadstone, will direct itself so as to lie in a magnetic north and south position, and the application of this discovery to direct the navigation of ships, have been attributed to various origins. The Chinese, the Arabs, the Greeks, the Etruscans, the Finns and the Italians have all been claimed as originators of the compass. There is little doubt that many writers on the history of the subject have lost sight of the fact that the ancients could and did make long voyages out of sight of land, using a steady wind to give them their direction and an occasional sight of the sun or stars to inform them of any change. When the compass made its appearance it was not at first used to steer by, but merely to check the direction of the wind when thick weather prevented the use of heavenly bodies.

A belief that the Chinese were the first inventors of the compass arose from legends of the use of a south-pointing chariot in which a human figure with outstretched arm always indicated the south. According to the first of these legends, the emperor Huang-ti fought a battle in the year 2634 B.C. against the rebellious prince Ch'ih-yu. The latter raised a great mist to screen his movements, but the emperor sent a south-pointing chariot to the head of his troops and this guided them through the mist so that the rebel was taken and executed. Stories of other chariots appear to have been added much later, and there is no evidence that any contained a magnetic element. It is much more likely that the guiding figure had a mechanical drive.

The Chinese traded in ships to the Persian gulf and the Red sea in the 9th century A.D., but there is no evidence that they used a compass. The fact remains that the earliest report of their use of the compass appears in a work entitled *P'ing-chou-k'o-t'an*. The date given is the end of the 11th century A.D.

When Europeans first penetrated into eastern seas it was noticed that the compasses used by the Chinese differed from and were inferior to their own. Some writers have suggested that the compass must therefore have been independently invented in Europe and in China, but there seems to be no reason why the designs used in the two places should not have progressed along different lines from a single stem.

It has also been claimed that the compass originated with the Arabs, their superiority in scientific learning and their early skill in navigation being adduced in support of the conjecture.

It has been asserted that the Arabs, Turks and Persians have no original name for the compass, it being called by them *bossola*, the Italian name, which shows that the thing signified is foreign to them as well as the word. The Rev. G. P. Badger, however, pointed out that the name of *bushla* or *busba*, from the Italian *bussola*, though common among Arab sailors in the Mediterranean, was very seldom used in the eastern sea—*da'irah* and *bait al-ibrah* (the "circle," or "house of the needle") being the ordinary appellatives in the Red sea, while in the Persian gulf *giblah-hamah* was in more general use. (*Travels of Ludovico di Varthema*, trans. by J. W. Jones, ed. by G. P. Badger, Hakluyt Society, note, pp. 31 and 32, 1863.) The earliest traced reference to the use of a compass by Arab sailors appears to have been made by Mohammed al-Awfi in a collection of Persian anecdotes written in 1232, and probably referred to a floating compass seen by him in 1220.

Bailak Kibdjaki, an Arabian writer, shows in his *Merchant's Treasure* (1282) that the magnetized needle, floated on water by means of a splinter of wood or a reed, was employed on the Syrian

seas at the time of his voyage from Tripoli to Alexandria (1242) and adds, "They say that the captains who navigate the Indian seas use, instead of the needle and splinter, a sort of fish made out of hollow iron, which, when thrown into the water, swims upon the surface, and points out the north and south with its head and tail" (Klaproth, *Lettre*, p. 57). By the time of the incursion of the Portuguese into eastern seas, the Arabs had become accomplished navigators with equipment at their command which compared favourably with that of Europe. João de Barros describes a map of all the coast of India, shown to Vasco de Gama by a Moor of Gujarat (about July 15, 1498), in which the bearings were laid down "after the manner of the Moors," or "with meridians and parallels very small [or close together], without other bearings of the compass; because, as the squares of these meridians and parallels were very small the coast was laid down by these two bearings of N. and S., and E. and W., with great certainty, without that multiplication of bearings of the points of the compass usual in our maps, which serves as the root of the others." Further, Jeronymo Osorio says that the Arabs at the time of Vasco da Gama "were instructed in so many of the arts of navigation, that they did not yield much to the Portuguese mariners in the science and practice of maritime matters." (See *The Three Voyages of Vasco da Gama*, Hakluyt Society, note to ch. xv by H. E. J. Stanley, p. 138, 1869.) Also the Arabs who navigated the Red sea at the same period are shown by Ludovico di Varthema to have used the mariner's chart and compass (*Travels*, p. 31).

In Scandinavian records there is a reference to the nautical use of the magnet in the *Hauksbók*, the last edition of the *Landnámabók* ("Book of Settlements"), "Floki, son of Vilgerd, instituted a great sacrifice, and consecrated three ravens which should show him the way [to Iceland], for at that time no men sailing the high seas had loadstones up in northern lands." Haukr Erlendsson, who wrote this paragraph about 1300, died in 1334; his edition was founded on material in two earlier works, that of Styrmir Kárasón (d. 1245), which is lost, and that of Hurla Thordson (d. 1284), which has no such paragraph. All that is certain is a knowledge of the nautical use of the magnet at the end of the 13th century.

It will thus be seen that the earliest authentic information concerning the use of the compass comes from China (c. A.D. 1100), from Arabia (A.D. 1220) and from Scandinavia (c. A.D. 1250), while, as will be shown, the earliest western European date is A.D. 1187. In any of these areas the compass may well have been known long before it was recorded. It is not, therefore, possible to state with any certainty where the first discovery occurred, and whether knowledge of the use of the compass was transmitted from one nation to another or whether it was the result of independent invention. For the early history of the compass and the many claims and theories as to its origin see A. Crichton Mitchell, "Chapters in the History of Terrestrial Magnetism," *Terrestrial Magnetism and Atmospheric Electricity*, 37:105-146 (1932), 42:241-280 (1937), 44:77-80 (1939), 51:323-251 (1946).

The earliest definite mention as yet known of the use of the mariner's compass in Europe occurs in a treatise entitled *De utensilibus* written by Alexander Neckam about 1187. He speaks there of a needle carried on board ship which showed mariners their course when the polestar was hidden. In another work (*De naturis rerum*, ch. xcvi) he writes, "Mariners at sea, when, through cloudy weather in the day which hides the sun, or through the darkness of the night, they lose the knowledge of the quarter of the world to which they are sailing, touch a needle with the magnet, which will turn round till, on its motion ceasing, its point will be directed towards the north" (W. Chappell, *Nature*, 14:147, 1876). The magnetic needle and its suspension on a stick or straw in water are clearly described in *La Bible Guiot*, a poem written about 1206 by Guiot de Provins, which states that through the magnet (*la manette* or *l'amanière*), an ugly brown stone to which iron turns of its own accord, mariners possess an art that cannot fail them. A needle touched by it and floated by a stick on water turns its point toward the polestar and, a light being placed near the needle on dark nights, the proper course is known. There are a number of similar references during the 13th century.

The earliest detailed work on the magnetic compass is contained in the remarkable *Epistola de magnete* of Petrus Peregrinus de Maricourt, written in 1269. The first part of the epistle deals generally with magnetic attractions and repulsions, with the polarity of the stone and with the supposed influence of the poles of the heavens upon the poles of the stone. In the second part Peregrinus describes first an improved floating compass with fiducial line, a circle graduated with 90° to each quadrant and provided with movable sights for taking bearings. He then describes a compass with a needle thrust through a pivoted axis, placed in a box with transparent cover, cross index of brass or silver, divided circle and an external alidade provided with a pair of sights.

The earliest type of mariner's compass probably consisted of a magnetized needle thrust through a crossbar of wood or reed so that it would float in a bowl of water. It is possible that there was an even earlier type in which an actual lump of loadstone was floated on a piece of board. The next step was to use a needle pivoted on a pin rising from the bottom of the bowl. At first only the north-south direction would be considered, then the points were marked in the bottom of the bowl and the instrument was kept turned until the north point painted in the bowl was under the north end of the needle. Finally a card, marked with the points required, was attached to the needle itself.

There is a tradition that the compass was first introduced into the Mediterranean by sailors from the port of Amalfi. The story first appeared in print about 1450, and during the next 150 years

FIG. 1.—(A) 18TH-CENTURY COMPASS CARD DIVIDED INTO POINTS AND HAVING ORNAMENTATION AT THE EAST POINT; (B) U.S. NAVAL COMPASS CARD MADE OF METAL WITH GRADUATIONS PERFORATED THROUGH IT

was gradually expanded, by steps which can be recognized, until it was said that the compass was invented by Flavio Gioia of Amalfi in 1302. The ease with which both name and date could be shown to be late interpolations soon threw discredit upon the whole tradition. It is, however, quite possible that there was some truth in it; Amalfi may have introduced the compass several centuries earlier, or may have learned to attach the card to the needle about the year 1300.

The *rosa ventorum* or wind rose is far older than the compass itself, and the naming of the eight principal winds goes back to the Temple of the Winds in Athens built by Andronicus of Cyrrhus. The earliest-known wind roses on the charts which accompanied the *portolani* or Mediterranean pilots almost invariably have the eight principal points marked with the initials of the principal winds, tramontana, greco, levante, sirocco, ostro, africo (or libeccio), ponente and maestro, or with a cross instead of an L to mark the east point. The north point, indicated in some of the oldest wind roses with a broad arrowhead or a spear, as well as with a T for tramontana, gradually developed by a combination of these, about 1492, into a fleur-de-lis, still almost universal. The cross at the east, or rather the ornamentation into which it developed, continued on British compass cards well into the 19th century (see fig. 1). Wind roses with these characteristics are found in Venetian and Genoese charts of the early 14th century and are depicted similarly by the Spanish navigators. The naming of the intermediate subdivisions making up the 32 points or rhumbs of the compass card is probably due to Flemish navigators, but they were recognized even in the time of Geoffrey Chaucer who in 1391 wrote, "Now is thin(e) Orisonte departed in xliiii

partiez by thi azymutz, in signification of xxiii. partiez of the world: al be it so that ship men rikne thilke partiez in xxxii" (*Treatise on the Astrolabe*, ed. by W. Skeat, Early English Text Society, 1872). Francesco da Buti, the Dante commentator, in 1380 says that sailors use a compass at the middle of which is pivoted a wheel of light paper, on which wheel the needle is fixed and the star (wind rose) painted. This is the earliest recorded reference to the compass card. The gimbals or rings for suspending the compass bowl, hinged at right angles to one another, have been erroneously attributed to G. Cardano, the proper term being *cardine*, that is hinged or pivoted. The earliest description of them dates from about 1537. The term binnacle, formerly bitacle, is a corruption of the Portuguese *bitacolo* denoting the housing enclosing the compass, and probably originated with the Portuguese navigators.

The earliest reference to a compass being used in a particular ship occurs about 1345 when "twelve stones, called adamants, called sailstones," were bought in Flanders for 6d. for the king's ship called "La George" (Sir N. Harris Nicolas, *History of the Royal Navy*, ii, p. 476, 1847). The name compass appears in about 1410 when the "Christopher" had "iiij compas j dyol" but it is possible that the word did not then have the modern meaning. The origin of the name is obscure but it is thought to have been first applied to the compasses attached to pocket sundials.

The improvement of the compass was a slow process. *The Libelle of Englyshe Polycye*, a poem of the first half of the 15th century, says with reference to Iceland (ch. x):

Out of Bristowe, and costes many one,  
Man haue practised by nedle and by stone  
Thider wardes within a litle while.

(Richard Hakluyt, *Principal Navigations*, p. 201, 1599).

From this it would seem that the compasses used at that time by English mariners were still of a very primitive description. William Barlow in his treatise *Magnetical Advertisements*, printed in 1616 (p. 66), complains that "the Compasse needle, being the most admirable and useful instrument of the whole world, is both amongst ours and other nations for the most part, so bunglerly and absurdly contrived, as nothing more." This plaint was echoed in very similar words by Matthew Flinders almost exactly 200 years later: "the compasses, even in the Royal Navy and to this day, are the worst constructed instruments of any carried to sea" (*Voyage to Terra Australis*, 1814). The form recommended for the needle by Barlow was that of a "true circle, having his Axis going out beyond the circle, at each end narrow and narrower, unto a reasonable sharpe point, and being pure steele as the circle it selfe is, having in the midst a convenient receptacle to place the capitell in."

During the 16th century, to get over the difficulty of pivoting the needle itself at the centre, two needles of iron wire were used, bent apart at the centre and joining at the ends so as to form an almost oval shape. By the middle of the 18th century this form had changed until the two wires were generally bent into the form of a parallelogram. The method of magnetizing was crude and the material used did not retain its magnetism. Difficulties were also caused by an inequality in the magnetic moment of the needles so that an error of direction often occurred. In 1766 Gowin Knight took out the first English patent for a compass. He perfected a method of using better steel for the needle and for giving it a greatly increased magnetic moment. He went back to the idea of a single needle with the cap for the pivot screwed into its centre. These compasses were a great advance on anything seen before. They were adopted by the Royal Navy and were copied in Germany.

Single flat needles became the usual custom until about 1840 when the admiralty compass committee of 1837 designed a new compass for the Royal Navy which was so successful that it was adopted by all the principal navies. In this compass four needles placed on edge were used, each being made of laminated steel plates. The needles were symmetrically arranged at such distances apart that the angle at the centre of the card between the similar poles of adjacent needles was 30°. This arrangement was chosen to give greater steadiness by equaling the moments of

inertia in the north-south and east-west planes. The researches of Capt. F. J. O. Evans and Archibald Smith, published in 1861, showed that this arrangement was also of value in preventing the introduction of certain compass errors.

The new compasses, though a considerable improvement over their predecessors, were still by no means perfect, being much affected by the vibration of steam vessels. As early as 1813 Francis Crow had proposed filling the bowl with liquid to damp out any oscillations of the needle. Many difficulties were encountered with this type of compass through leakage or expansion of liquid, discoloration of paint, difficulty of replacing a worn pivot, etc. Though such compasses at first had too many disadvantages to allow their adoption in ships they were extensively used for row boats, whose jerky motion made any other type of compass useless. Many attempts were made to produce satisfactory liquid compasses and great advances were made by E. S. Ritchie in 1862 and W. R. Hammersley in 1866. The former patented a float which, being attached to the card, took most of the weight off the pivot, thereby reducing friction and wear and removing the necessity for frequent replacement or sharpening. Hammersley invented an expansion chamber and this, together with improved methods of jointing, did much to prevent leaks or bursting of the bowl.

Ritchie's compass was eventually accepted for the U.S. navy but in the Royal Navy liquid compasses were introduced for use only in bad weather and during gunfire.

In 1876 Sir William Thomson, afterward Lord Kelvin, broke new ground by inventing the light type of dry-card compass. His equipment was ultimately adopted in the Royal Navy but it must be admitted that this step was encouraged more by the advantage of his binnacle, which had full provision for compass correction, than by the advantages of his compass. The adoption of this compass gave the liquid compass a setback and it was not until 1906 that liquid compasses were finally adopted by the Royal Navy. The compass then introduced by Capt. L. W. P. Chetwynd, R.N., differed only in minor details from the compass used today. (W. E. My.; Ad. H.)

**Variation.**—During the 15th century it became apparent that the compass needle did not point to the true north but made an angle with the true meridian. This angle is called the variation by seamen, the alternative term, declination, being liable to cause confusion with the declination of heavenly bodies. Claims have been advanced that the Chinese knew of the existence of variation at the end of the 11th century and that it was referred to by Roger Bacon in his *Opus minus* in 1266. The references on which these claims are based are, however, extremely vague. Although the first authentic record of a definite value for the variation was made by Georg Hartmann in a letter of 1544 referring to observations of 1510, there is no doubt that the existence of variation must have been known a century earlier. The discovery of variation has been attributed to Columbus, but there can be no doubt that its existence was known before he commenced his voyages. Some of the compasses which he used on his second (1493) voyage had their needles mounted askew on the cards to correct for variation.

William Gilbert (*De magnete*, 1600) was the first man to put forward the hypothesis that the directive power of the compass was the result of the fact that the earth itself was a great magnet, but he had thought that variation was caused by the magnetic attraction of land masses. Gerhardus Mercator had earlier attributed the fact of variation to the situation of a magnetic pole in about 85° N. and longitude 180° from the meridian of the Azores, then used as a prime meridian because of the supposed absence of variation along it.

While charts showing the variation are said to have been made by Alonzo de Santa Cruz about 1536, the first world variation chart of modern type was produced by Edmund Halley in 1701. The earliest of these charts were intended for use in determining the longitude from the variation, a scheme dear to the hearts of many inventors of the period.

Later charts were intended as an aid to navigation to enable ships to know what allowance should be made in shaping courses

and also to enable them to obtain the deviation by subtracting the variation from the observed total compass error. Captain Evans' chart was the forerunner of the regular admiralty variation charts which are published from time to time. Variation charts have, of course, been published in other countries.

### LATER DEVELOPMENTS IN THE MARINER'S MAGNETIC COMPASS

The term magnetic compass covers a number of apparently dissimilar instruments, all of which perform the function of determining the direction of the horizontal component of the earth's magnetic field. They are conveniently divided into two groups: (1) pivoted-needle compasses; (2) inductor compasses. Into the pivoted-needle group fall the mariner's compass, aircraft compasses and surveying instruments. The mariner's compass is subdivided into the liquid compass and dry-card compass types. Inductor compasses, aircraft compasses and surveying instruments are discussed under *Other Types of Compasses*, below.

**The Liquid Magnetic Compass.**—This compass is now almost universally used by mariners.

FIG. 2.—BRITISH NAVAL LIQUID COMPASS

The card is usually of mica with the graduations reproduced photographically on the underside and backed with a thin coat of white paint. The system of marking generally used is a clockwise graduation in degrees right around the card from 0° at north to 359°. This graduation has now generally replaced the earlier one by quadrants running from 0° at north and south in each direction to 90° at east and west. In some compasses graduation into points in addition to degrees is used, while a few fishermen still cling to compasses graduated in points only.

The card is attached to a float which carries the magnets or "needles." Both bar magnets and ring magnets are in common use. When bar magnets are used, there must be an even number, two being the most usual. With such a system, the magnets must of course be parallel with the north-south diameter of the card, and they are placed so that the similar poles of the magnets subtend an angle of 60° at the centre of the card.

If more than two bar magnets are used, the angles subtended are modified accordingly; e.g., a four-magnet system requires an angle of 90° subtended by the poles of the outer magnets and 30° by the poles of the inner magnets. A ring magnet must be set with its magnetic axis (or diameter) parallel with the north-south diameter of the card. All these systems have a moment of inertia that is constant about any line in the horizontal plane, and thus

any tendency to unsteadiness when the ship is rolling or pitching is considerably reduced. Certain errors, to which a single compass needle is subject when compass correction in an iron ship is carried out, are also avoided.

The system of card, float and magnets must be as light as possible to avoid friction at the pivot. It is also made bottom heavy in order to counteract the downward pull of the vertical component of the earth's magnetic field, which would cause the system to tilt. At the centre of the card is a metal cap containing a jewel which rests on a pivot rising on a stem from the bottom of the bowl. The pivot is tipped with iridium.

The bowl is filled with a mixture of alcohol and water which will neither freeze nor boil at temperatures normally encountered. To prevent the verge glass (see fig. 2) from bursting or bubbles from forming because of the inevitable expansion and contraction of the liquid, the bottom is attached by a corrugated ring which adjusts itself to the change of volume. To avoid the effect of liquid swirl, the card is considerably less in diameter than the bowl. The bowl is closed at top and bottom by sheets of glass so that the card can be illuminated from below and read from above. A pointer, known as the lubber's point, projecting from the inside of the bowl, indicates the compass course of the vessel. The bowl is hung by pivots in the athwartship line in a ring, known as a gimbal ring or cardan ring, which is itself hung in fore-and-aft pivots. A lead weight on the bottom of the bowl ensures that the bowl will remain horizontal whatever the heel of the vessel. The pivot point should be at the intersection of the lines joining the gimbal axes and should, together with the lubber's point and card, lie in the same horizontal plane through them.

**The Dry-Card Compass** now used differs from its predecessors in that the card is very much lighter and the moment of the magnets less. The card is made of paper secured to an aluminum ring, usually ten inches in diameter. This ring is fastened to a small central one by radiating silk threads while small needles, generally eight in number, are hung below the card, also by silk threads. The inner ring fits over a cap containing the jewel, the cap being in this way easily renewable. The pivot on which the cap rests is slid into a hollow column in the bowl so that it also can easily be withdrawn. These compasses with their large cards are easy to read (liquid compasses with cards in excess of seven inches in diameter are unwieldy). They are, however, very liable to be disturbed by vibration or shocks and, once deflected, are slow to settle again. The card must be protected from these effects, and so the bowl is usually hung from complicated spring suspensions. The liquid compass has, therefore, very considerable advantages over the dry-card type.

**Azimuth Instruments.**—A ship usually has at least two magnetic compasses unless a repeating magnetic compass is fitted. One, known as the steering compass, is used for directing the ship on the appropriate course.

The standard compass is that by which the ship is navigated, all bearings being taken from it and all courses shaped. Hence an all-round view and freedom from magnetic interference are to be aimed at in selecting its position in the ship. To enable bearings to be taken with accuracy, the standard compass is fitted with an azimuth instrument which rotates either round a central pin in the glass cover of the compass or on the outer verge ring of the compass. These instruments are of several types. The simplest form consists of two sight vanes mounted on a framework and joined by a thread. The vanes can be trained until they are in line with the object required and the eye must then be transferred to read off the card graduation which comes under the thread. In the next form a prism is fitted at the eye vane so that the required object can be seen direct at the same time that the card graduation is seen in the prism. As the near edge of the card is read instead of the far, it requires a second set of graduations 180° out of phase with the normal one. In another type a prism is fitted below the object sight vane, thus eliminating the need for additional graduations, though it is usual to have a second set of figures reversed. If the prism is at a height above the card equal to the radius of the card, the eye vane can be dispensed with since small errors in directing the instrument have no effect.

on the bearing observed in the prism. By the use of a magnifying prism a large image is obtained. With this type it is usual even to reduce the object sight vane to a mere V in the top of the prism. It is easy to use and can be handled with speed and accuracy. In all these types a mirror is hinged to the object sight vane or magnifying prism so that the image of sun or star can be reflected down to the line of sight.

In the Kelvin type of instrument a tube, carrying a 60° prism at the top with a lens below it, is fitted in an inclined position over the far end of the card from the observer. Two methods of use are available. For low objects the eye is kept down and the card is seen reflected in the prism while the object is observed above it. In the second method, which can be used for high or low objects, the head is raised so that the card can be seen directly through the lens while the prism is turned until the object is reflected in it. This instrument is particularly useful for observing stars in altitude.

Azimuth instruments are also made in which the sight vanes are replaced by a telescope. An optical arrangement built into the telescope enables card and object to be seen in the same eyepiece at the same time. Other instruments incorporate an auxiliary arrangement of cylindrical mirror and prism by means of which the sun can be made to throw a line of light onto the card, thus indicating its bearing.

**The Binnacle.**—The mariner's compass is mounted in a pedestal, usually of cylindrical form, called a binnacle. This binnacle has, at the top, bearings to take the gimbal pivots. It is fitted to take the various magnets and soft-iron bodies necessary for the correction of the compass for the magnetic effects of the ship's hull. These correctors usually consist of an iron sphere on each side, a vertical iron bar, called the Flinders bar, usually on the fore side, and magnets placed in vertical and in fore-and-aft and athwartship horizontal positions. In some binnacles a number of holes or racks are provided for the horizontal magnets; in others they are placed in carriages which are either slid up and down a vertical tube or are raised and lowered by gearing. The binnacle is fitted with a hood to protect the compass from the weather, and with some form of illumination. In some ships it is necessary to place the compass overhead in order to get it farther from the steel of the ship: the card is graduated on the underside and the compass is illuminated from above.

A device known as a projector binnacle is used in submarines, and in a simpler form in some surface vessels. In the former case, the compass bowl is mounted outside the steel hull of the vessel and an image of the card is projected optically onto a screen in front of the helmsman. The optical system is contained in a pressure-tight tube, which forms the binnacle where it protrudes from the hull. Such a device enables a reasonable magnetic position to be found in a submarine. The projector binnacle for surface vessels enables the standard compass, on the compass platform, to be used for steering by a helmsman on the deck below. He is provided with a viewing screen upon which an image of the compass card is projected.

**Repeating Magnetic Compasses.**—It is often undesirable to place the compass at the navigating or steering position because of the unsatisfactory magnetic conditions there. In such circumstances a repeating magnetic compass may be used; *i.e.*, a compass which transmits the reading of a master compass unit to one or more repeaters. Thus the master compass containing the magnet system may be placed in a position where the magnetic conditions are suitable. Since an indication of the vessel's heading is required by various modern navigational aids (*e.g.*, radar), a repeater mechanism may be fitted in the instrument concerned.

There are several well-tried methods of obtaining transmission from a pivoted-needle compass, their common feature being that the magnet system is not subject to any disturbing torque, the actual work being done by a follow-up system. Bridge circuits are the most usual and the most accurate; they give a null indication when operating correctly. Capacity bridges may be operated by a small capacitor mounted on the magnet system, the excitation being preferably at a high frequency. Inductive bridges may be operated by varying the coupling between coils in the cir-

cuit of a radio-frequency oscillator; resistance bridges can be employed in which the relative position of card and bowl electrodes determines the balance or otherwise of the bridge, the compass liquid acting as a resistive path for electric current, and photocells may be energized by a light beam shining through a slot in the card. In all these systems, zero balance of the bridge is associated with a definite alignment between a follow-up member (which may be the bowl itself) and the compass card, the output from the bridge being amplified and used to drive a follow-up motor geared to the follow-up member. Thus the latter, be it the bowl or some external element, is electrically locked to the card and regardless of the movement of the ship is a north-seeking device driven by electrical power. Any transmitting system, therefore, can be coupled to the follow-up member and distant repeaters will faithfully reproduce the ship's head as indicated by the compass card.

Transmission can be obtained from a pivoted-needle compass by the aid of an inductor system, as mentioned below, and inductor compasses themselves, by their very nature and their associated electrical circuits, are inherently repeating compasses.

Another repeating system is that in which a very light synchro transmitter is coupled to the compass needle by a slave magnet, providing a universal and self-aligning coupling. This, unfortunately, imposes an appreciable torque on the needle and certain cyclic errors are introduced, but where accuracy of a high order is not required this system has advantages by virtue of its simplicity.

**The Gyromagnetic Compass.**—Reference will be made below to the acceleration errors which are a source of trouble in aircraft (and to some extent in small, fast ships). These errors are produced when the compass system relates itself to the false vertical during acceleration. By mounting the compass, which must be nonpendulous (*e.g.*, a double-pivoted needle or an inductor element), on a stable platform that is always maintained horizontal by a gyroscope, acceleration errors are largely avoided. One such compass consists of a saturable inductor mounted on a vertical gyroscope. The magnetic element therefore is always horizontal and is unaffected by the vertical component of the earth's magnetic field. The headings given by this compass are correctly related to the direction of magnetic north in the horizontal plane.

The combination of a vertical gyroscope and a magnetic compass is not always a convenient arrangement from the point of view of weight and space. Another system uses the azimuthal stability of a horizontal gyroscope. Such a gyroscope provides the primary heading reference and by conventional means provides transmission to repeaters and to a comparison device whereby the gyroscope heading and magnetic north, as indicated by a compass system, are referred to one another. Should there be any difference a correcting signal is initiated which is employed either to correct the transmission so that it is driven into alignment with the compass element or to precess the gyroscope which in turn aligns the transmitting system with the compass element. Drifting of the gyroscope is thus continually corrected by comparison with magnetic north.

Any perturbations of the compass system, due to accelerations and the like, result in the gyroscope heading being referred to a "false north." Since the compass system is designed to have a comparatively short period of oscillation, and since the correcting signal need only be large enough to ensure complete control of the gyroscope drift rate, very little disturbance of the repeater system takes place during successive oscillations of the compass. The false control signal is unable to deviate the repeater system appreciably before the return swing of the compass reverses the control signal, and so stability of headings is assured in spite of accelerations acting on the compass system. Pivoted needles and inductors are both equally suited to gyromagnetic compasses. The former provide a convenient comparison means by coupling the follow-up element of a repeating magnetic compass (*see above*) to the gyroscope's transmission system. Unless the follow-up element is correctly aligned, a signal is generated which provides the necessary correction by acting upon the gyroscope

or its transmission. By this means the follow-up system is aligned with the compass system.

Similarly an inductor system may provide the magnetic heading information, comparison between it and the gyroscope's transmission system being made by, for instance, a resolver or sine-cosine potentiometer coupled to the gyroscope or its transmission. Incorrect alignment again gives rise to a signal which persists, and is used for correction, until the gyroscope's transmission is driven into alignment with the magnetic compass datum.

**Ship's Magnetism and Deviation of the Compass.**—If any magnetic material is brought near to a magnetic compass it will tend to deflect the needle from the magnetic meridian. The angle of deflection, known as the deviation, will depend on the relative strengths of the earth's and of the deflecting magnetic fields and on their relative directions. Although the fact that iron brought close to a magnetic compass will deflect it was noted as early as 1538 by João de Castro, it was not generally known to seamen until well into the 19th century, and any irregularity in the pointing of the compass was attributed to the imperfections of its manufacture or of the loadstone with which it had been "touched." During his voyage to Australia in 1801–03, Flinders became the first man to carry out proper experiments into the phenomenon and to propose a corrector, the vertical bar of soft iron which now bears his name. He stated that the deviation in H.M.S. "Investigator" depended upon the sine of the ship's head and upon the dip. (He should have said the tangent of the dip.) On his return to England Flinders urged the admiralty to have experiments conducted in a number of ships to discover whether their compasses obeyed the same rules and these were carried out in 1812.

The admiralty compass committee of 1837, besides designing a compass, laid down rules to ensure that it would be fitted in a place as free as possible from magnetic disturbance. Because of adverse reports on a system of correction devised by Sir G. B. Airy, the Royal Navy preferred to observe and apply the errors of the compass rather than to attempt to correct them. This practice remained the almost universal rule until the introduction into the navy of the Kelvin compass in 1889, although for many years it had been found necessary to reduce the deviations to manageable proportions, in the larger ships, by magnets let into the deck. In merchant vessels the practice of compass correction was much more usual. In 1824 Siméon Denis Poisson published in France a mathematical investigation into the deviation of the compass. The theory was taken still further by Smith in 1851, and between 1855 and 1865, in conjunction with Captain Evans, he carried out a series of investigations into the behaviour of magnetic compasses in ships the results of which appeared in a number of papers read to the Royal society and other bodies and in the *Admiralty Manual for Ascertaining and Applying the Deviations of the Compass*, first published in 1862.

The effect of the magnetism of the ship on the compass can be divided into two parts, that resulting from the magnetism which is more or less permanent in character (sometimes referred to as the hard-iron effect) and that caused by magnetism transiently induced which changes with the direction of the ship's head and with its location on the earth (sometimes called the soft-iron effect). For convenience, the magnetic field of the ship may be resolved into three components, fore and aft, athwartship and vertical. The errors due to hard iron can be corrected by placing permanent magnets in the vicinity of the compass in the three directions stated so that the field resulting from each magnet cancels the corresponding component of the disturbing field. The hard-iron or permanent magnetic effect is subject to changes caused by aging and change of geographical position but in general it settles down by the time a ship has been in service about a year, so that thereafter it is necessary to correct the ship's compass only about once a year. If a ship is struck by lightning or subjected to severe shocks because of the explosion of shells, bombs, etc., its magnetic state may undergo a considerable change. The effect of this magnetic disturbance may take several months to settle down.

Permanent magnets were first proposed by Airy but fell into some disrepute, particularly in the Royal Navy, because their use

was not properly understood. At one time it was usual to fit a single magnet let into the deck at an angle to the fore-and-aft line to do the work of both sets of horizontal magnets. Lord Kelvin's binnacle was one of the first in which proper provision was made for accommodating horizontal magnets. By the 1950s the practice had been introduced of using a pair of magnets pivoted at their centres like a pair of scissors. When the scissors are closed with unlike poles together the magnets neutralize one another, but as they are opened the ends form two parallel virtual magnets, whose strengths increase as the distance between the ends is increased. Finally, when the scissors are completely open the strength of the two full parallel magnets is obtained. This type of corrector is frequently employed for the correction of aircraft compasses. One form of the corrector has a pair of crown wheels, each with a magnet attached, so mounted that the two wheels turn in opposite directions when a pinion, geared between them, is rotated. Three pairs of wheels and magnets can be used to correct for permanent magnetism in three mutually perpendicular directions, viz., fore and aft, athwartship and vertically.

The effect of soft iron or induced magnetism is slightly more complicated since it depends on whether the main direction of the iron under consideration is fore and aft, athwartship or vertical and whether the nearest magnetic pole to the compass is before or abaft, to one side or above or below it. The horizontal components of soft iron are corrected by soft-iron spheres placed one on each side of the compass and the vertical components by the Flinders bar already mentioned. The spheres, having magnetism induced in them by the earth's field corresponding to that induced in the ship, produce a correction which holds good for all values of the earth's horizontal force.

The correction of the soft-iron effect by masses of soft iron was first suggested by Airy. He preferred to use boxes filled with soft-iron chain, nails, etc., a method still used by the Dutch navy in 1940. Spheres were first tried in the Royal Navy in 1854 and in 1860 the Liverpool compass committee advocated cylinders placed end-on to the compass. Spheres were finally adopted in the Royal Navy with the introduction of the Kelvin binnacle. It has been stated earlier that the spheres are magnetized by induction from the earth's magnetic field. This is not the only factor, since in practice the spheres are partly magnetized by induction from the compass needles, the amount caused by the needles depending on their magnetic moment and their distance from the spheres and being independent of latitude. With the Kelvin compass the magnetic moment is so low that the induction caused by the needles is negligible, but with some liquid compasses this is not the case. It follows that if a ship in which the spheres have been properly adjusted proceeds to the equator (where the induction in the ship's hull is greater because of the greater horizontal force of the earth) the induction in the spheres caused by the earth increases proportionally but that caused by the compass needles remains unaltered so that part of the error remains uncorrected.

In the French navy the errors to be corrected became so large because of the nonobservance of rules for design of compass positions, that it became quite impracticable to fit spheres large enough to obtain sufficient correction. Lieut. C. Morel, therefore, introduced the fitting of a small soft-iron bar so close below the compass needles that it received nearly all its induction from them, that from the earth being negligible (*Revue maritime*, 185:100, 1910). With such a bar very large errors can be corrected but the adjustment has to be repeated after quite a small change of latitude. The method was adopted by the French navy and by the German, where the position of the bar or bars was varied so that they were sometimes above and sometimes beside the compass instead of below it. The bar was also occasionally used in the Dutch navy and in the Italian navy where it was also used in conjunction with spheres. In Great Britain it has been used for the correction of compasses in armoured fighting vehicles where the error to be corrected is usually large and the change of latitude difficulty does not apply.

In order to correct the compasses of a ship a process known as swinging is performed. The spheres and Flinders bar are first placed by estimation. In an old ship the results of observations

on previous voyages may be available; in a new one the positions can sometimes be fairly closely estimated since sister ships require the same length of bar and almost the same sphere positions. The vertical magnets are then placed so that the vertical magnetic force at the compass position is slightly less than that ashore. For this a heeling error instrument, which is a modified form of dip needle, is used.

The ship is then placed with her head on north, east, south and west in turn, the horizontal magnets being adjusted until there is no error, the fore-and-aft on east or west and the athwartship on north or south. Afterward the ship is placed on one of the quadrantal points (northeast, southeast, southwest or northwest) and the spheres are moved closer to or farther away from the compass until there is no deviation. It is advisable to check each of the corrections given above on opposite headings and, if any error is found there, to readjust by removing half the error. In a ship in which the compass is placed off the centre line or where magnetic material in its vicinity is unsymmetrical it may also be necessary to slew the spheres. Finally, the ship is turned slowly round while the residual errors are observed and tabulated to give the deviation card. It is usual to observe on every other point of the compass; *i.e.*, a total of 16 readings is taken. In some navies it is customary to observe every 15°. The whole revolution of 360° should be carried out slowly and steadily and should take at least an hour. The tabulated deviations are used for the correction of courses steered and bearings observed and are also subjected to mathematical analysis. From this analysis it is possible to diagnose the errors made in the correction and also any unusual magnetic forces acting on the compass.

During World War II it became necessary to protect ships from magnetic mines. One of the protective measures used was to encircle the ship with a coil carrying electric current which, by setting up an opposite magnetic field, opposed the magnetic field of the ship so that the resultant field below the hull was too weak to operate a mine. These coils, while they were energized, naturally changed the magnetic field at the compass position and it became necessary to correct for their effect.

To this end each binnacle was fitted with coils which when energized produced magnetic fields in three directions, *viz.*, fore and aft, athwartship and vertical. (The U.S. navy preferred to use its horizontal axis coils inclined at 45° on each side of the fore-and-aft line.) Each coil was fed from a potentiometer which was supplied from the same source as the main coil. In this way the current in the corrector coil could be adjusted to produce a field to neutralize the magnetic field caused by the main coil. This adjustment was made during a second swing with protecting coils switched on after the compass had been adjusted in the ordinary way with the coils switched off.

**The Compass Position in a Ship.**—To ensure that the magnetic compass of a ship shall operate with sufficient accuracy, care must be taken in designing the bridge or other position in which it is to be fitted. Steel plating may have magnetic poles of such strength that if placed too close, their effect cannot conveniently be corrected and even if sufficient correction can be applied their strength may change appreciably. This is particularly the case if the plating is subjected to excessive heating, as in the case of that of a funnel, when the strength of the magnetic field produced may be subject to considerable fluctuation. In addition, the changes of magnetic field because of moving materials (cows and davits and the permanent magnets in telephones and loud-hailers) and the existence of occasional electromagnetic fields when electrical instruments are in use must be considered.

In the Royal Navy a set of rules relating to the "safe distance" from the compass of magnetic and electrical material and equipment has been laid down.

### OTHER TYPES OF COMPASSES

**Aircraft Compasses.**—The use of pivoted-needle compasses in aircraft emphasized the errors due to acceleration. Let the craft be supposed to turn in a clockwise direction at constant speed; then, since the magnet system of the compass is bottom heavy, it will no longer hang in the true (gravitational) vertical, but will

swing outward and take up its position with respect to a false vertical, the resultant of gravitational and centrifugal accelerations. As the heading of the craft passes through magnetic north, the magnets swing out to the west and the system is acted upon by a component of the earth's vertical force which, making it act as a dipping needle, introduces easterly deviation; *i.e.*, the magnet system turns in the same direction as the craft. Similarly, when the heading of the craft passes through south, the magnet system is deflected to the west; *i.e.*, it turns in the opposite direction to that of the craft. As the heading of the craft passes through east or west, the magnet system is tilted in such a way that the vertical component of the earth's field does not turn the magnet system but merely alters the value of the directive force.

The above phenomenon is known as northerly turning error and its effect is to minimize the turns through north and to exaggerate the turns through south, irrespective of the direction of turning of the craft. The error is almost imperceptible in ships except for such vessels as fast patrol boats, but in aircraft, with higher speeds, it attains considerable proportions. If, when the craft turns through north, the error is equal to the angle turned through, no turn is indicated by the compass; if the error is greater than the turn, the compass will indicate an apparent turn in the wrong direction. The error is at maximum when the heading is north or south and is gradually reduced on other headings until it becomes zero on east and west.

Again, if the craft is accelerating on a straight course, the magnet system will tend to lag behind and align itself again in the false vertical. Once more, the effect of the earth's vertical force will cause the magnet system to turn, but in this case the effect is maximum on east and west courses and zero on north and south. This effect is known as east-west acceleration error.

These errors are observed as actual errors only while the craft is turning or accelerating. The more general effect, however, is that they cause oscillations of the magnet system when the craft is steering a nominally straight course. For instance, yawing can be considered to consist of a number of short turns which will result in alternating turning errors causing the magnet system to swing from side to side of the meridian. Rolling and pitching will introduce accelerations of the compass position which will again

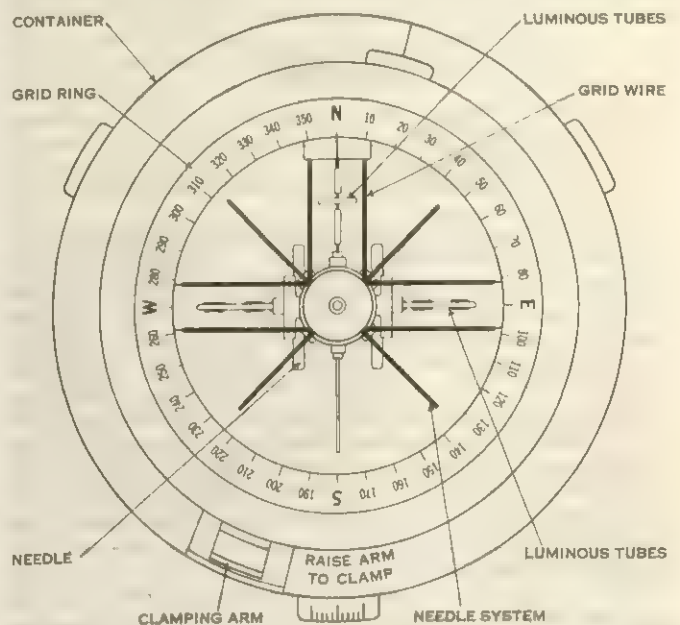

FIG. 3.—PLAN VIEW OF AIRCRAFT COMPASS SHOWING GRID AND MAGNET SYSTEM

result in oscillations of the magnet system. The effect of yawing and rolling will be at a maximum on north or south courses and the effect of pitching will be at a maximum on east or west courses.

In a ship the acceleration errors are usually not large. Magnets of a fair size can be used together with a large enough card to be read with considerable accuracy. In the case of aircraft the

accelerations caused by random motion when on straight courses are very much greater than in the case of a ship. The problem is complicated even further by the requirement that for use in aircraft the size and weight of the compass shall be at an absolute minimum.

In order that the magnet system may be as steady as possible under adverse conditions, its natural period of oscillation is made long and heavy damping is introduced; e.g., by the immersion of the system in liquid.

The type of compass which will give the steadiest reading in an aircraft is one which is aperiodic.

A better solution of the problem of acceleration error is provided by the gyromagnetic compass (*see above*). Nevertheless, many aircraft use liquid-damped pivoted-needle compasses, and

CROWN COPYRIGHT RESERVED

FIG. 4.—EMERGENCY (E-TYPE) COMPASS FOR AIRCRAFT

it is customary to provide what is known as grid steering in order to facilitate the holding of a given course. A rotatable ring, carrying luminized grid wires in the form of a  $\perp$  (*see fig. 3*), is fitted to the compass bowl, the upright limb being directed to the zero mark of a circumferential scale of degrees on the ring. The magnet system has no card but, instead, luminous glass tubes which are fastened to the east-west and the northern half of the north-south damping filaments, the northern end being indicated by a cross. To steer a given course, the grid ring is turned until the desired course is indicated on the scale against a lubber's point in the bowl. The aircraft is then turned until the glass tubes on the magnet system lie within and parallel to the grid wires. It is then only necessary to steer the aircraft so that the glass tubes and grid wires are kept parallel to one another.

Vibration is a much greater problem in an aircraft than in a ship, and steps must be taken to ensure that the aircraft vibration is not transmitted to the compass bowl lest variable errors be introduced.

The importance of the liquid-damped compass in aircraft has been diminished by the advent of the gyromagnetic compass, and the modern tendency is to fit a far less refined type of liquid compass in aircraft for use in emergency. The bowl of one such type is roughly spherical, about two inches in diameter and made of polystyrene (*see fig. 4*). An edge reading card is supported at the

centre of the bowl by the usual pivot and jewel. Silicone fluid is used as a damping medium. The aircraft's heading is ascertained by reading the card against a vertical lubber's line on the surface of the bowl facing the pilot. The temperature range throughout which it is necessary for an aircraft compass to function correctly is much greater than that for the functioning of a ship's compass, and the same compass liquid is not suitable for both. The liquids normally used in aircraft compasses are a mixture of 95% pure ethyl alcohol and 5% methyl alcohol (special care must be taken to ensure that the paint and other materials used inside the compass bowl are unaffected by the action of this compass liquid), a silicone fluid of an appropriate viscosity and various forms of kerosene or white spirit.

The correctors used to compensate for the effect of ferromagnetic material in the aircraft are usually of the scissors type. Errors due to soft iron in an aircraft are usually so small that no devices are required for their correction.

**Vehicle Compasses.**—Adaptations of aircraft compasses are sometimes used for land vehicles; the British North Greenland expedition (1952-54) and the Commonwealth Transantarctic expedition (1955-58) were so equipped. The electrical equipment in such vehicles is usually a serious source of compass deviation.

**Surveying Instruments.**—Compasses for both land- and sea-borne surveys, the measurement of angles, the determination of variation and the like may be either liquid or dry instruments. The usual surveyor's compass is essentially an azimuth instrument and has a pivoted compass card and magnet at the centre of a bowl, adapted to be rotatably secured to the top of a tripod. The bowl carries a sighting device for training toward a given object.

The compass designed by the admiralty compass committee in 1842 is still regarded as a most reliable and useful surveying compass. It has a dry card with four magnets and an azimuth device which can be read by verniers to one minute of arc.

An instrument related to the surveying compass is the so-called datum compass. This is primarily used for ascertaining the magnetic heading of an aircraft during compass adjustment, and is capable of a high order of accuracy. It comprises a magnetic element with either a 360° card as in a conventional compass or a bearing plate that may be related to magnetic north by alignment with and reference to the magnetic element. The card or bearing plate is read with an optical magnifier and the line of sight is determined by viewing a suitable mark through a telescopic azimuth sight. These instruments are distinguished by the fact that they are refined and calibrated so that their errors do not exceed a few minutes of arc, and are ten times more accurate than the usual navigational compasses. Theodolite compasses, which are usually single-pivoted needles in a trough or tube and which are used to align the theodolite in the magnetic meridian, are included in the category of datum compasses.

A related group, though markedly less refined, are the prismatic marching compasses, which may be dry or liquid according to their quality, and which are used for map reading in the field, setting a line of march and similar purposes.

**Inductor Compasses.**—The pivoted-needle compass so far discussed indicates direction by virtue of the fact that a magnetic needle rests along the direction of the magnetic field of the earth. The inductor compass, also, determines direction by reference to the earth's magnetic field, but by measuring its strength. The earliest English patent for such a compass appears to be that of L. Dunoyer in 1907. In the simplest form a small coil with its axis horizontal is mounted on a vertical spindle. When the spindle is rotated the coil cuts the horizontal component of the earth's magnetic field and consequently acts as a dynamo, generating an electrical supply whose voltage may be measured. The direction and strength of this voltage will depend on the position of coil and brushes relative to the direction of the earth's field. The brushes can be rotated by hand and their position indicated on a dial. The method of using the compass is to turn the dial until the required course is indicated on the dial and then to alter the course of the craft until the voltmeter reads zero. There are many adaptations of this device, the sensitivity being enhanced in some cases by the addition of a highly permeable magnetic core.

to the rotating coil. All these instruments are inclined to be bulky and of necessity use rapidly rotating parts. Mechanically they are unsuitable for modern ships and aircraft and have been superseded by what is known as the saturable inductor compass.

This measures the intensity of an ambient field, and is an entirely static device. Its operation depends on the readily saturable property of highly permeable alloys such as permalloy C and mumetal, and the consequent production of harmonic distortion in an alternating current supply to a solenoid wound about a core of such material. The rate of change of flux threading the solenoid (or back electromagnetic force) is abruptly changed as the

FIG. 5.—DIAGRAM OF SATURABLE INDUCTOR

alternating current drives the core material in and out of saturation twice in every cycle. When an ambient magnetic field exists along the core, the instants of saturating and unsaturating are different for the positive and negative half cycles of excitation and thus by suitable detecting instruments the presence and strength of a magnetic field may be determined. Two such inductors may be connected in a bridge circuit, in which case the fundamental excitation frequency may be canceled in each half of the bridge, leaving only the harmonic distortion which arises when an external magnetic field is present. This distortion gives rise to a back electromagnetic force predominantly second harmonic in nature but having a long series of higher even harmonics of smaller amplitude. Filters suppress all but the second harmonic, the magnitude of which is proportional to the applied field. This second harmonic mode is the most common in compass practice, though fundamental frequency systems have been proposed. Another technique, the measurement of the peak height of the voltage pulses produced in the bridge system, is more generally used in magnetometers and magnetic anomaly detector systems.

The second harmonic inductor for compass use (see fig. 5) is most conveniently constructed in the form of two adjacent parallel cores of highly permeable material, whose length is great compared with their diameter. Each has an axial winding, and these windings are connected in opposition and supplied from a source of alternating current. So far similar to the bridge circuit, the pair of wound cores is, however, enclosed in a secondary winding of a large number of turns and from the terminals of this a second harmonic voltage proportional to the axial magnetic field is obtained. Such an inductor may be used as a compass if provided with a follow-up mechanism devised to drive it to a null position—in which case the inductor would be directed east-west.

For accurate indication a card and gimbal system would be necessary, and it must be borne in mind that an inductor compass is subject to precisely the same kind of tilting and acceleration errors as a pivoted-needle compass. A compass of the type described still has the objections of bulk and weight, the presence of rotating parts, slip rings and the like. If, however, two or more inductors are used to measure the components of the horizontal field of the earth along several directions in a ship or in an aircraft, the relation of the fore-and-aft line to magnetic north can be found by combining the several voltages. For example, one inductor is in the fore-and-aft direction and another in the athwartship direction. The two vectors are combined in a two-phase re-

solver, the rotor of which may be adapted to seek a null position which is related to the direction of the earth's magnetic field with respect to the fore-and-aft line of the vessel. The detector system, except for its gimbal suspension, is stationary and has no moving parts. It is light and compact. The inductor compass can be combined with a pivoted-needle compass in order that it may operate in a stronger ambient field than that of the earth. By this arrangement certain tilt errors are avoided and a repeating system from a pivoted-needle compass is made available.

The Sun Compass is an instrument for obtaining an approximate direction from the direction of the sun. It is most easily considered as working in the reverse manner to a sundial. The sundial is carefully set up with its meridian accurately in the north-south direction and the shadow of its gnomon, or style, falling on the dial indicates the time. With the sun compass, on the other hand, the dial is turned until the shadow indicates the correct time and the meridian of the dial then indicates the true north-south line. The time set on the dial is the apparent time, i.e., the time by the sun at the place of observation, and should not be confused with the time normally indicated by clocks which, for convenience, is mean time. Apparent time depends on the longitude, and the actual length of the apparent day varies slightly throughout the year.

In a simple type of sun compass the gnomon, or pin, is vertical and its shadow falls upon a horizontal dial plate. This plate is graduated to show the times at which the shadow will make definite angles with the north-south line.

Different dial plates must be used for different latitudes and for different declinations of the sun so that, to obtain a sufficient degree of accuracy, a set of 13 plates is required for each band of about 3° of latitude. If the gnomon is made adjustable so that it can be moved in a north-south direction to allow for the date, i.e., the declination, one plate can be used in all latitudes and at all seasons. In this case the latitudes are indicated by a family of ellipses while the time lines become a family of hyperbolas. The meridian line indicates the true direction when the shadow of the gnomon falls on the intersection of the correct latitude and time curves. When the instrument is used in a vehicle to steer a predetermined course, the dial plate is set with its meridian line at the correct angle with the centre line of the vehicle, and the vehicle steered so that the shadow of the gnomon falls in the correct direction.

The astrocompass is a type of sun compass in which the dial plate is tilted about an east-west axis at an angle with the horizontal equal to the co-latitude. The gnomon and a target plate are rotated about the centre of the dial plate, their direction being indicated on a time scale. They are also tilted relatively to the dial plate by the angle of declination of the body being observed. Use of the compass involves keeping the time scale set and the shadow of the gnomon on the target. To observe stars, hour angle is used instead of time.

Several years before the outbreak of World War II in 1939 the value of a sun compass was recognized by officers serving in armoured fighting vehicles in the Egyptian desert. Various types were brought into use and proved of great value during the Libyan campaigns.

E. May, *Compass Adjustment* (1951). During the 19th century a number of important papers appeared in the *Philosophical Transactions of the Royal Society*, *Journal of the Royal United Service Institution*, *Transactions of the Institution of Naval Architects*, etc. On aircraft compasses see E. Brook Williams and W. J. V. Branch, *Air Navigation: Theory and Practice* (1952). (W. E. MY.; L. S. B.; AD. H.)

**COMPASS PLANT**, a common weed (*Silphium laciniatum*) of the interior of the North American prairies, which takes its name from the position assumed by the leaves. These turn their edges approximately to north and south, thus avoiding the exces-

sive midday heat while getting the full benefit of the milder morning and evening rays. The compass plant, also called pilotweed and rosinweed, belongs to the family Compositae.

Another member of the same family, *Lactuca scariola*, which has been regarded as the parent species of the cultivated lettuce (*L. sativa*), behaves in the same way when growing in dry exposed places; it is a native of Europe and northern Asia and has been widely introduced into North America.

**COMPENSATION**, a term applied in law to a number of different forms of legal reparation. It is due in England for improvements made by a lessee (see LANDLORD AND TENANT); it is due workmen for accidents occurring in the course of employment (see WORKMEN'S COMPENSATION); and it is due a person whose property or person is injured by the negligent conduct of another (see TORT). Compensation is also due an owner of property which is taken by the government or a public utility (see EMINENT DOMAIN; CONFISCATION AND EXPROPRIATION). For applicability of the doctrine to the property of nationals of one state seized by another, see NATIONALIZATION. See also references under "Compensation" in the Index volume. (A. DM.)

**COMPENSATION INSURANCE:** see WORKMEN'S COMPENSATION.

**COMPÈRE, LOYSET** (c. 1450–1518), one of the most charming among the Flemish contemporaries of Josquin Desprès. Probably a native of St. Omer, from 1474 to 1475 he was a member of the chapel of Galeazzo Sforza, duke of Milan. By 1486 he was in Paris as "singer in ordinary" to Charles VIII. He died, Aug. 16, 1518, at St. Quentin. Apparently a pupil of Jean d'Okeghem, Compère was a transitional figure, uniting the elegance of Guillaume Dufay with the humanism of Desprès. His most popular works were his chansons and motets. Two complete Masses survive, with 26 motets, 4 Magnificat, 52 chansons and 2 frottole.

**BIBLIOGRAPHY.**—Modern editions of chansons and motets in A. Smijers, *Van Ockeghem tot Sweelinck*, vol. iv (1942); H. Hewitt (ed.), *Harmonice Musices Odhecaton A* (1946). See also O. Gombosi, "Ghizeghem und Compère," in *Festschrift für Guido Adler* (1930).

(B. L. Tr.)

**COMPETITION, ECONOMIC.** In business and to the general public, competition in the market for any product or service means the absence of monopoly (*q.v.*) on either the selling or buying side, and likewise the absence of government intervention in the market process. To the economist competition means much more, especially when qualified by adjectives such as pure or perfect. It denotes a number of competitors who are well informed and who act independently of each other, the number being so large that no one of them can raise the market price of his output by restricting his sales, or lower the price of his input of resources by restricting his purchases. There must be free and relatively easy entry into and exit from the market or industry in question. The product should also be standardized and uniform so as to assure complete knowledge of its price and quality and guarantee against more than one price prevailing at any time in a single market.

**Oligopoly and Monopolistic Competition.**—Consider two hybrid forms, oligopoly and monopolistic competition. Each oligopolist is large enough to affect by his own sales or purchases the price of something which he sells or buys, but he still faces one or more business rivals. In monopolistic competition, the number of firms is large and there is free entry, but the product of each firm is differentiated either naturally or artificially (as by advertising), so that each firm may charge a different price from its rivals without forcing them out of business or being forced out itself. The business world and the general public consider oligopolistic and monopolistically competitive situations as being competitive, although competition usually concentrates in these cases on quality, on service, etc., rather than on price. There is usually more conscious competitive spirit between oligopolists (*e.g.*, the leading automobile manufacturers in the U.S.) or between monopolistic competitors (gasoline stations on opposite corners) than between pure competitors (wheat farmers on neighbouring farms). The economist usually lumps oligopoly and monopolistic competition together with monopoly under the head of imperfect competition.

On the other side of the market, buyers' monopoly is usually called monopsony. This term, corresponding to oligopoly, has not, however, become popular. The situation where monopolists and monopsonists face each other across the bargaining table is called bilateral monopoly. A group of ostensibly independent economic units acting collectively is called a cartel (*q.v.*) on either the buying or selling side of the market. A trade union, for example, is a labour cartel.

More than taxonomy or classification is involved here, because the traditional defense of competition applies almost entirely to the pure form. Furthermore, most of the so-called wastes of competition are more characteristic of oligopoly and monopolistic competition than of pure competition.

**Merits and Demerits.**—The traditional defense of competition in the 19th-century liberal tradition is made on grounds of optimum allocation of resources. It can be shown by formal economic theory that, given the population, tastes, resources, distribution of wealth, economic institutions and available technologies in a society, pure competition normally allocates resources ideally in the long run. By ideal is meant a situation in which: (1) no more of any product could be produced without using up resources worth more than the price of the product; (2) no more of any resource could be used without producing additional goods worth less than the price of the resources itself; (3) no resource could be transferred from one use to another without diminishing the value of the total product; and (4) no product could be produced at a lower average cost. Costs are taken here to include normal profits; *i.e.*, returns on resources supplied by the enterpriser himself.

This competitive ideal, never realized in competitive practice, has impressed a number of socialist writers to the point of being advocated as a policy aim for a planned economy. A socialist planning board could (it has been held) approximate the results of perfect competition more closely than an imperfectly competitive enterprise system.

On the negative side, the traditional liberal economists' case for competition claimed that it avoided the principal evils of monopoly on the one hand and governmental management on the other. The principal evil of monopoly (or imperfect competition) as they saw it was the profitability of raising prices in order to obtain greater gains by restricting output and violating the canons of ideal allocation of resources listed above. The principal evils of governmental management were held to be the lack of incentives to economic efficiency and progress and the danger of substituting dictatorial restrictions on civil liberty (not exclusively economic) for the operations of the market in fulfilling centralized economic plans.

Yet even at the zenith of laissez-faire economics (roughly the third quarter of the 19th century) there was always dissent from the competitive prescription by socialist and reformist writers. (Karl Marx's economic writing dates mainly from this period.) Certain of the grounds for dissatisfaction, including some developed much later, are the following:

The competitive system guarantees neither an equitable income distribution nor a "social minimum" income for all. If one starts from a distribution of wealth not in conformity with ethical ideals, the results of competitive economy will conform to the actual distribution rather than the ethical ideals. Bluntly, cream for the princess' cat will be produced ahead of milk for the beggar's baby. Price control, rationing and allocation are often advocated to offset the distribution of wealth and property, to assure the poor a larger share in consumption goods than the free market provides, even after the income distribution is modified by fiscal measures.

In speaking of cost in connection with competitive pricing or the competitive allocation of resources, one refers only to private costs actually borne by the enterpriser, not social costs which may be greater or less. The smoke nuisance is a common example of a social cost not usually reflected in the private cost of a smoky factory. Subsidization is suggested when the private costs exceed the social costs, and special taxes in the opposite case.

In industries with heavy fixed investments or sunk costs, like coal or steel, high-cost or inefficient firms do not in fact withdraw

from business or reduce their capitalization until they have been losing money for a prolonged period. Pure competition in these cases sometimes leads to chronically sick industries, with overproduction driving prices below the cost of even the efficient concerns. Workable competition, which usually involves some measure of price and output control by the industry or by a public agency, may offer a preferable outcome.

Similarly, in industries where demand fluctuates violently, and where capacity expands only slowly in response to increases in demand, it may be wise to stabilize prices and maintain excess capacity in operation during slack periods, which the competitive price mechanism will not do. Industries involved directly and indirectly in war production are specially subject to this consideration.

Technological development may be more rapid if financed in part by public funds, or by monopoly or oligopoly profits, or if the firm which takes the risk of introducing it is protected from imitative competition by its monopoly or oligopoly position. A patent system is itself a restriction on competition, but it is often an inadequate protection in cases of this kind, since many economic innovations are not patentable. It is not surprising to find many underdeveloped countries relying on government enterprises, public corporations or charters of monopoly in sectors critical to their rates of growth, even when their general economic philosophy is a competitive one.

In order to secure the maximum economies of large-scale production, plants must be large enough in some industries to lead to monopoly or oligopoly. Or, to put it in reverse, one can approximate pure competition in some industries only by sacrificing some of the benefits of technological progress.

Granted that real incomes have risen under economies which are primarily competitive, there is dissatisfaction with competition for failure to guarantee full employment and stability of the general price level at the same time. In modern economic thought, these problems are viewed as aggregative, that is, beyond the province of individual markets or industries, competitive or otherwise. Responsibility for the level of employment and prices is thought to rest primarily with the society's money, credit, fiscal and international trade policies, in all of which public control plays an important part.

The task of public monetary and fiscal authorities in maintaining full employment without inflation is easier when the economy is more freely competitive, since monopolistic pressure groups can sometimes force price increases which would not otherwise occur in periods of high employment or cut output in slack times when prices would have fallen under pure competition. On the other hand, direct governmental price and output controls are more effective in an oligopolistic or monopolistic economy, where similar controls exist on a private basis even in normal times.

**Long-Term Trend.**—As societies progress, an increasing proportion of the national income and product takes the form of publicly produced goods and services, particularly of government services, civilian and military. This seems to hold even in private-enterprise economies like that of the U.S., in which the federal government's economic role increased drastically after the turn of the 20th century and particularly after 1930, until the public sector came to account for from one-fourth to one-third of the national product. The obverse of this trend is a relative, although not an absolute, fall in the importance of the private economy, which includes the competitive sector.

Within the private economy itself there is much discussion of the relative importance of the competitive and the monopolistic elements. The classical economists treated *laissez faire* and free competition as largely synonymous because they regarded private monopoly, oligopoly included, as resulting primarily from public interference with free trade. They had in mind the royal charters of monopoly granted by the Tudor and Stuart kings of England, the protection of domestic monopolies by tariff legislation and so on. They foresaw the rapid demise of monopoly in a regime of *laissez faire* and of international free trade. Even in modern times it is possible to ascribe much of the persistence of monopoly and oligopoly to legislation encouraging trade unions and cartels,

enlarging the scope and coverage of patents and trade-marks, legalizing resale-price maintenance and permitting corporations to hold each other's securities. Public regulations and purchasing policies are also accused of favouring large, well-established firms as against their small, less well-established competitors.

At the same time, it has become an article of faith among economic planners that, with the passage of time, competition becomes steadily more oligopolistic and steadily closer to monopoly. This principle was stated originally by Marx. The main reason for such a decline of competition is the heavy capital investment required to build a modern automobile factory or steelworks or to secure public acceptance for a new brand of soap or cigarettes. Entry, in other words, remains legally free to outsiders but becomes economically closed to them.

Statistical evidence, while inconclusive, supports neither of these extreme positions. In the American case, special effort has been made to preserve competition by the enactment and sporadic enforcement of antimonopoly legislation such as the Sherman, Clayton and Federal Trade Commission acts. Yet the relative importance of large-scale industry appears to be growing, as measured by the percentage of total manufacturing output or employment concentrated in the largest 50, 100 or 200 manufacturing corporations. But at the same time, the number of small independent firms is rising along with the size of the largest ones, and less than half of the 100 giants of 1900 are among the 100 giants of the 1960s. The largest corporations, constantly expanding into related fields, also find themselves competing (oligopolistically) with each other. Consider, for example, electrical home appliances, where there is competition between the large radio, electrical machinery, automobile and flour-milling companies, in addition to the large department stores and mail-order houses.

One authority speaks of countervailing power as arising in the form of the large merchandising companies (with monopoly power on the buying side) protecting the public from the exactions of large manufacturers with monopoly power on the selling side. The importance of interindustry competition is also great in many oligopolistic fields, as for example between motion-picture, radio and television entertainment, and likewise the competition of the used product in other oligopolistic fields, most notably automobiles. Figures taken exclusively from manufacturing, moreover, are somewhat misleading as to the course of concentration. Economies, in the process of development, appear to shift in relative emphasis from manufacturing industry to the (usually smaller-scale) service trades after a certain point in development is reached—in the U.S., after World War I. However, such service industries as telephones, radio and newspapers may also become both large and monopolistic.

Improvement in the means of transportation and communication affected the state of competition in a variety of ways. "People of the same trade seldom meet together, even for merriment and diversion," said Adam Smith, "but the conversation ends in a conspiracy against the public, or in some contrivance to raise prices." In modern times it is much easier for "people of the same trade," ostensible competitors, to meet together or otherwise to communicate and collude against the public, even internationally, than it was in the 1770s when Adam Smith was writing. At the same time, improvements in transportation and communication widened markets enormously in terms of area and population. These improvements completely eliminated the monopoly power of many a petty local merchant or moneylender. As a result of these improvements, a few conspicuous giant concerns may be as competitive throughout a country or a continent, despite their size, as a great number of smaller firms used to be, taken a few at a time within individual towns or counties.

Another complex effect of development, particularly of communication, has been the rise of the new industries of advertising and selling. These are expensive industries, in which so much of the efforts of A go to cancel the efforts of B that a considerable amount of economic waste inevitably results. It cannot be estimated with any reliability what proportion of the increased information supplied to buyers by competing sellers (or to sellers by competing buyers) is actually both true and relevant. It is also

quite uncertain whether the net results of advertising and selling have been favourable or unfavourable to competition as against monopoly. That is to say, it is not known whether advertising and selling have operated primarily to open up a broader range of rational choices than existed before or to confirm consumers in set prejudices and forestall experimentation with competing products.

Trade advertising and selling, directed to informed businessmen as intermediate buyers, is predominantly true and relevant and does increase the degree of competition, but this is only a small fraction of the total advertising and selling industries. It is probably likewise true that, whatever may be the effects of advertising and selling on competition within single industries, they have intensified the scope and the severity of interindustry competition for the consumer's pound or dollar.

For legal aspects see **MONOPOLY: Legal Aspects**; **FAIR TRADE LAWS**; **FEDERAL TRADE COMMISSION**; **INTERSTATE COMMERCE**. See also **BUSINESS CODES**; **CARTEL**; and see references under "Competition, Economic" in the Index.

**BIBLIOGRAPHY.**—The classical case for competition in industry dates from Adam Smith, *Wealth of Nations*, book iv (1776). Its standard presentation is perhaps John Stuart Mill, *Principles of Political Economy*, book v (1848). A restatement, with significant modifications, makes up A. C. Pigou, *Economics of Welfare*, part II, 3rd ed. (1929). Of recent works maintaining the beneficence of substantial degrees of monopoly in developing capitalist economies, three may be mentioned as influential: Joseph A. Schumpeter, *Capitalism, Socialism, and Democracy*, ch. v-vii (1942); J. Kenneth Galbraith, *American Capitalism: The Concept of Countervailing Power* (1952); and Sumner H. Slichter, *The American Economy* (1948).

On imperfect and monopolistic competition, the standard references are E. H. Chamberlin, *Theory of Monopolistic Competition* (1933); Mrs. Joan Robinson, *Economics of Imperfect Competition* (1933); and William Fellner, *Competition Among the Few* (1949). A recent development, following John von Neumann and Oskar Morgenstern's *Theory of Games and Economic Behavior* (1944), has been the analysis of oligopoly and bilateral monopoly using game-theoretical principles. An example is Martin Shubik, *Strategy and Market Structure* (1959). Applying competitive theory to socialist planning, see B. E. Lippincott (ed.), *Economic Theory of Socialism*, by Oskar Lange and Fred M. Taylor (1938); and A. P. Lerner, *Economics of Control* (1944).

The thesis that competition leads to monopoly is expounded or suggested in, e.g., A. A. Berle and Gardiner C. Means, *The Modern Corporation and Private Property* (1933); Robert A. Brady, *Business as a System of Power* (1943); Arthur R. Burns, *The Decline of Competition* (1936); Thurman Arnold, *The Folklore of Capitalism* (1937); and Joseph Steindl, *Small and Big Business* (1946). A contrary view is maintained in George J. Stigler, *Five Lectures on Economic Problems*, ch. v (1949); and G. Warren Nutter, *Extent of Enterprise Monopoly in the United States, 1899-1939* (1951).

Antitrust legislation and its enforcement are advocated as controls over the imperfections of competition in Corwin D. Edwards, *Maintaining Competition* (1949); Henry C. Simons, *Economic Policy for a Free Society*, ch. II-v (1948); Britz Machlup, *Political Economy of Monopoly* (1952); and Donald Dewey, *Monopoly in Economics and Law* (1959). For the other point of view, in addition to the works of Schumpeter and Galbraith cited above, reference should be made to an influential essay by John Maurice Clark, "Toward a Concept of Workable Competition," reprinted in American Economic Association, *Readings in the Social Control of Industry* (1942).

A variety of studies are also available of competition and monopoly within individual industries, both national and international. For the United States, the Temporary National Economic Commission (1938-41) provides a particularly rich mine of source material, partially summarized in David Lynch, *Concentration of Economic Power* (1946). As a start on industry studies, with emphasis on the U.S., see Walter Adams (ed.), *Structure of American Industry*, 2nd ed. (1954); L. W. Weiss, *Economics and American Industry* (1961); William H. Nicholls, *Imperfect Competition Within Agricultural Industries* (1941); or Alfred R. Oxenfeldt, *Industrial Pricing and Market Practices* (1951). The problem of entry of new firms is discussed most fully in Joe S. Bain, *Barriers to New Competition* (1956). On the problem of advertising, which transcends individual industries, the standard work is Neil Borden, *Economic Effects of Advertising* (1942). (Mn. B.)

**COMPIÈGNE**, a town in the Oise département, northern France, is situated on the left bank of the Oise, 76 km. (47 mi.) N.N.E. of Paris by road. Pop. (1962) 23,833. The centre of the town is the Place de l'Hôtel de Ville, which is connected with the bridge over the Oise (rebuilt 1949) by the Rue Solferino. The *hôtel de ville*, with its fine façade surmounted by an elegant belfry, is late Gothic. The church of St. Antoine (13th and 16th centuries) has fine Renaissance windows, and that of St. Jacques

dates from the 13th and 15th centuries. A Gothic cloister, which houses the municipal library, is all that remains of the abbey of St. Corneille. For a long time prior to 1870 Compiègne was one of the French royal residences. The magnificent palace, at which *Son et Lumière* is presented, is a rich art museum. It was built mainly by Louis XV and was restored by Napoleon I. One façade looks toward the town while the other faces the beautiful park extending to the great forest of oak and beech which was formerly considered part of the defenses of Paris. Compiègne is situated on the main railway from Paris to Brussels and is an important tourist centre. There are foundries, machinery and a milk-bottling works, and the industries include oil and soapmaking, automobile tires and biscuitmaking.

Mentioned as Compendium for the first time in 557, but existing before that, Compiègne was the site of many assemblies and councils under the Merovingian kings. In 833 Louis the Pious was deposed there. Charles the Bald enlarged the town and founded the abbey of St. Corneille. Compiègne became a commune in 1153. Joan of Arc was made prisoner there by the Burgundians, and several treaties were signed at the palace. In 1814 Compiègne resisted the invading Prussian troops stubbornly. Under Napoleon III the palace was the residence of the court during the hunting season. The headquarters of the German army in 1870 and 1871, the town was occupied by the Germans again in World War I and bombarded in 1918. The Armistice was signed on Nov. 11, 1918, in Marshal Foch's personal railway coach at a point 6 km. E.N.E. of Compiègne, in the forest near the village of Rethondes. The coach was preserved there as a monument, and on June 22, 1940, during World War II, the Franco-German Armistice was signed in it, in Hitler's presence. Having later removed the coach to Germany, the Germans destroyed it in April 1945 to prevent its recovery by the advancing Allies. Compiègne was liberated by the Allies on Aug. 30, 1944. (M. DE LA M.-C.)

**COMPLAINT**, in law, the plaintiff's initial pleading, corresponding to the libel in admiralty, the bill in equity and the petition in civil law. The complaint, called a declaration at common law, consists of a title, a statement showing venue or jurisdiction, one or more counts containing a brief formal exposition of the facts giving rise to the claim asserted and a demand for relief. Thus it informs the defendant of the plaintiff's claim and initiates the pretrial process of narrowing the case to one or more sharply defined issues of law or fact. At common law and under early procedural codes the task of defining the issues was performed solely by the pleadings, but modern procedural systems have utilized pretrial conferences and deposition and discovery procedures as well for this purpose. See **PRACTICE AND PROCEDURE**. (C. E. Cl.)

**COMPLEMENT**. In general the complement of an entity is that which with the given entity makes up a whole. In geometry the complement of an angle A is that angle which when added to A makes a right or 90° angle (see **ANGLE**; **TRIGONOMETRY**). In the theory of aggregates the complement of an aggregate S is the aggregate which remains when S is taken away from the aggregate U which forms the domain of discourse. See **SET THEORY (THEORY OF AGGREGATES)**; **LATTICE THEORY: Complements**. (L. M. G.)

**COMPLEX IONS**: see **CO-ORDINATION COMPOUNDS**.

**COMPLEX NUMBERS**. Since certain algebraic equations such as  $x^2 + 1 = 0$  have no solutions in real numbers, early mathematicians were led to consider purely formal solutions involving square roots of negative numbers.

Thus Heron of Alexandria (c. A.D. 100) obtained the solution  $\sqrt{-63}$ , and Girolamo Cardan (1545) wrote  $40 = (5 + \sqrt{-15})(5 - \sqrt{-15})$ . These numbers were considered to be quite meaningless, and the term imaginary was applied to them. They have since become indispensable in several branches of modern mathematics and have applications in mechanics and electricity.

**Geometric Representation**.—If  $i$  is by definition a solution of the equation  $x^2 + 1 = 0$ , numbers of the form  $a + bi$  where  $a$  and  $b$  are real are called complex (Carl Friedrich Gauss, 1832).

The modern development of complex numbers began with the discovery of a geometric interpretation for them. This

FIG. 1.—THE COMPLEX NUMBER

was indistinctly set forth by John Wallis (1685), and in completely satisfactory form by Caspar Wessel (1799).

Wessel's work received no attention, and the geometric interpretation was rediscovered by Jean Robert Argand (1806) and again by Gauss (1831). It is frequently called the Argand diagram (fig. 1).

Just as the real numbers represent points on a line, the complex numbers can be put into corre-

spondence with the points on a plane. The multiples of  $i$  are called purely imaginary numbers and are plotted as points on the imaginary axis perpendicular to the axis of reals at the O-point. Then the number  $a + bi$  corresponds to the point  $P$  where  $OP$  is the diagonal of the rectangle whose sides are  $a$  and  $bi$ . If  $a + bi$  is multiplied by  $-1$ , its corresponding line or vector  $OP$  is rotated through  $180^\circ$ . Similarly if  $a + bi$  is multiplied by  $i$ , its vector is rotated through  $90^\circ$ . Thus two successive multiplications by  $i$  produce the same effect as one multiplication by  $-1$ , so that in this sense  $i^2 = -1$ .

**Logical Justification.**—The first satisfactory introduction of the complex numbers was given by Sir William Rowan Hamilton (*Trans. Royal Irish Acad.*) in 1835, although Gauss afterward stated that the same idea had occurred to him in 1831.

Consider the set of all ordered couples  $\alpha = (a_1, b_1)$ ,  $\beta = (a_2, b_2)$ , of real numbers where  $\alpha = \beta$  means that  $a_1 = a_2$  and  $b_1 = b_2$ . Define the operations of addition and multiplication of couples by the equations

$$\alpha + \beta = (a_1 + a_2, b_1 + b_2), \quad \alpha\beta = (a_1a_2 - b_1b_2, a_1b_2 + a_2b_1).$$

It can easily be shown that these couples combine according to the following rules:

$$\begin{aligned} \alpha + (\beta + \gamma) &= (\alpha + \beta) + \gamma, & \alpha(\beta\gamma) &= (\alpha\beta)\gamma, \\ \alpha + \beta &= \beta + \alpha, & \alpha\beta &= \beta\alpha, \\ \alpha(\beta + \gamma) &= \alpha\beta + \alpha\gamma. \end{aligned}$$

The couples of the form  $(a, 0)$  form a subset of the set of all couples which is abstractly identical with the set of real numbers. If  $(a, 0)$  corresponds to  $a$ , and  $(b, 0)$  corresponds to  $b$ , then  $(a, 0) + (b, 0)$  corresponds to  $a + b$ , and  $(a, 0) \times (b, 0)$  corresponds to  $ab$ . In this sense the real numbers are contained among these couples, and it may be written  $(a, 0) = a$ . In particular,  $(0, 0) = 0$  and  $(1, 0) = 1$ . If  $k$  is real,  $k(a, b) = (ka, kb)$ . For every couple  $\alpha$ ,  $\alpha + 0 = \alpha$  and  $\alpha \times 1 = \alpha$ . For every  $\alpha = (a, b)$  there is a couple  $-\alpha = (-a, -b)$  such that  $\alpha + (-\alpha) = 0$ ; and for every  $\alpha \neq 0$  there is a couple  $1/\alpha = (a/(a^2 + b^2), -b/(a^2 + b^2))$  such that  $\alpha \times (1/\alpha) = 1$ .

Thus the couples form a number field. All of the other rules of arithmetic which are valid for all fields are consequences of those enumerated. If one denotes the couple  $(0, 1)$  by the letter  $i$ , then  $i^2 = -1$  and

$$\alpha = (a, b) = a + bi.$$

These couples are precisely the complex numbers.

Another logical development of the complex field was given by Augustin Louis Cauchy (*Comptes Rendus*, Paris) in 1847. Consider the set of all polynomials

$$f(i) = c_0 + c_1i + c_2i^2 + \dots + c_ni^n$$

with real coefficients in the indeterminate  $i$ . Two polynomials are defined to be equal if they give the same remainder upon division by  $i^2 + 1$ . Thus every polynomial is equal to a polynomial  $c_0 + c_1i$  of the first degree in  $i$ . Addition and multiplication are defined in the usual way. That is,

$$(a_1 + b_1i)(a_2 + b_2i) = a_1a_2 + (a_1b_2 + a_2b_1)i + b_1b_2i^2.$$

Upon dividing this product by  $i^2 + 1$ , the remainder  $a_1a_2 - b_1b_2 + (a_1b_2 + a_2b_1)i$  is obtained, which is therefore equal to the product. Since  $i^2 + 1$  gives the remainder 0 upon division by  $i^2 + 1$ , it is true that  $i$  is a solution of the equation  $x^2 + 1 = 0$ .

The laws of arithmetic are as readily provable as in Hamilton's approach.

It is significant that it is not possible to define a complex number separately from all other complex numbers. The complex field can be defined either by Hamilton's method or by Cauchy's method; a complex number is an element of the complex field.

## Properties of the Complex Field.

Although the complex numbers appear to have been introduced to obtain a solution of the equation  $x^2 + 1 = 0$ , it is true that every equation with real coefficients, and indeed every equation with complex coefficients, has a complex root. This theorem, frequently called the Fundamental Theorem of Algebra, was proved by Gauss in his doctoral thesis (1799). It follows immediately that every equation of degree  $n$  has exactly  $n$  solutions, not necessarily distinct.

**The Fundamental Operations.**—Reference was made to the graphic representation of the complex numbers. The number  $a + bi$  can be made to correspond to a point on the plane, or to the line segment or vector from the origin to this point. If the latter point of view is adopted, it is true that the sum of two complex numbers corresponds to the diagonal of the parallelogram whose edges are the summands. Since directed physical magnitudes such as forces and velocities add by the parallelogram rule, it is apparent that complex numbers are well suited for their computation.

Multiplication of complex numbers is best treated through their polar representation (Roger Cotes, 1710; Abraham de Moivre, 1730; Leonhard Euler, 1743). If  $r$  represents the distance  $OP$  from the origin to the point  $a + bi$ , and if  $\theta$  is the angle from the positive  $x$ -axis to  $OP$ , then

$$a + bi = r(\cos\theta + i\sin\theta) = r \operatorname{cis} \theta.$$

The number  $r$  is called the absolute value (Karl Weierstrass) or modulus (Cauchy) of  $a + bi$ , and  $\theta$  is called the argument or phase.  $\operatorname{cis} \theta$  is an abbreviation for  $\cos\theta + i\sin\theta$ .

By the usual definition of multiplication,

$$r_1 \operatorname{cis} \theta_1 \cdot r_2 \operatorname{cis} \theta_2 = r_1 r_2 \operatorname{cis} (\theta_1 + \theta_2).$$

That is, the absolute value of a product is equal to the product of the absolute values of the factors, and the argument of the product is equal to the sum of the arguments of the factors. This leads to a simple graphic method

of multiplying two complex numbers  $a + bi$  and  $c + di$ . Construct a triangle upon the real unit segment with one of the vectors, say  $a + bi$ , as the other side. Construct a similar triangle upon the other vector  $c + di$ . The corresponding side to  $a + bi$  of this second triangle will represent the product  $(a + bi)(c + di)$ .

Since every equation such as  $x^n - (a + bi) = 0$  has  $n$  complex solutions, it follows that every complex number has  $n$  complex  $n$ -th roots. De Moivre's theorem states that

$$(r \operatorname{cis} \theta)^n = r^n \operatorname{cis} n\theta, \quad r \operatorname{cis} \theta = (\sqrt[n]{r} \operatorname{cis} \frac{\theta + 2k\pi}{n})^n,$$

$$k = 0, 1, 2, \dots, n-1.$$

Thus to find the  $n$ -th roots of  $r \operatorname{cis} \theta$ , draw a circle of radius  $\sqrt[n]{r}$  and draw a radius whose argument is  $\theta/n$ . This is one root. Divide the circumference into  $n$  equal parts, and draw the  $n$

FIG. 2.—ADDITION OF COMPLEX NUMBERS

FIG. 3.—MULTIPLICATION

equally spaced radii of which the first root is one. These radii are the  $n$ -th roots of  $r \operatorname{cis} \theta$ .

The power function in the complex field is, except in special cases, multiple-valued. That is,

$$(r \operatorname{cis} \theta)^{1/n} = q \operatorname{cis} \xi$$

where  $q$  and  $\xi$  are defined by the equations

$$\xi = s \sin \varphi \log r + s(\theta + 2\pi n) \cos \varphi,$$

$$\log q = s \cos \varphi \log r - s(\theta + 2\pi n) \sin \varphi, \quad n = 0, \pm 1, \pm 2, \dots$$

**Automorphisms.**—Mathematicians have been bothered by their inability to draw any genuine distinction between the numbers  $i$  and  $-i$ . The number  $a - bi$  is called the conjugate (Cauchy) of the number  $a + bi$ .

The conjugate of a sum is equal to the sum of the conjugates, and the conjugate of the product is equal to the product of the conjugates of the factors. In modern terminology, it is said that the correspondence between  $a + bi$  and  $a - bi$  is an automorphism of the complex field. The complex solutions of an equation with real coefficients occur in conjugate pairs.

FIG. 4.—ROOTS OF A COMPLEX NUMBER

Numbers of the form  $a + bi$  where  $a$  and  $b$  are rational constitute the Gaussian complex field. The numbers of this type where  $a$  and  $b$  are rational integers form an integral domain or ring very like the ring of ordinary rational integers or whole numbers.

The norm (Gauss) of  $a + bi$  is  $a^2 + b^2$ , and the norm of a product is equal to the product of the norms of the factors. The numbers of norm 1 are the units, namely 1,  $-1$ ,  $i$  and  $-i$ .

A number which is neither 0 nor a unit is called composite or prime according as it can or cannot be written as a product of two numbers neither of which is a unit. There exists a Euclid algorithm in this ring. That is, if  $\beta \neq 0$  and  $\alpha$  are two numbers of the ring, there exist two other numbers  $\kappa$  and  $\rho$  such that  $\alpha = \beta\kappa + \rho$  where the norm of  $\rho$  is less than the norm of  $\beta$ . Then every two numbers have a greatest common divisor expressible linearly in terms of the numbers. Consequently the Fundamental Theorem of Arithmetic holds for this ring: Every number  $\neq 0$  is factorable into a finite number of prime numbers and, save for unit factors and the order of the factors, this representation is unique.

If  $p$  is a rational prime of the form  $4k + 1$ , it is the product of two distinct conjugate complex primes; a rational prime of the form  $4k + 3$  is a complex prime; and  $2 = i(1 - i)^2$  where  $1 - i$  is a complex prime. Much of ordinary number theory carries over to the complex integers.

**Quaternions.**—In 1843 Hamilton generalized the complex field to the algebra of real quaternions  $a + bi + cj + dk$  where  $i^2 = j^2 = k^2 = -1$ ,  $ijk = -1$ . Most of the ordinary laws of arithmetic hold for such numbers except that the order of multiplication is not usually immaterial.

In the hands of Josiah Willard Gibbs and Oliver Heaviside and others, the quaternion algebra has been developed into modern vector analysis, a method which is of great importance in mechanics, electricity and other branches of applied mathematics. (See NUMBER; NUMBER SEQUENCES.)

**Hypercomplex Numbers.**—This term is applied to numbers of the type  $a_1 e_1 + a_2 e_2 + \dots + a_n e_n$  where the  $a$ 's are numbers of a field, the  $e$ 's are linearly independent with respect to this field, and  $e_i e_j = c_{ij1} e_1 + c_{ij2} e_2 + \dots + c_{ijn} e_n$ . Complex numbers and quaternions are special examples. The associative law of multiplication is usually assumed, but not the commutative law. (See ALGEBRAS [LINEAR].)

**Functions of a Complex Variable.**—One of the most extensive and useful branches of mathematics is the theory of functions of a complex variable. Let  $z = x + iy$  where  $x$  and  $y$  are

real variables and  $i^2 = -1$ . Then  $w = u + iv$  is a function of  $z$  if  $u$  and  $v$  are functions of  $x$  and  $y$ . This function is analytic (or regular, or holomorphic or monogenic) if  $u$  and  $v$  are differentiable and if the Cauchy-Riemann conditions hold, viz.

$$\partial u / \partial x = \partial v / \partial y, \quad \partial u / \partial y = -\partial v / \partial x.$$

This theory is considered extensively elsewhere (see FUNCTIONS, ANALYTIC).

**COMPLINE** (Lat. *completorium*, "the completion"), in the Roman Catholic Church (and in Anglican religious orders), is the last hour of the divine office, said before retiring. See BREVIARY; HOURS, CANONICAL.

**COMPOSITAE**, the name given to one of the largest families of flowering plants. It includes more than 900 genera and over 14,000 species. In North America over 200 genera are represented by many species distributed over the whole country.

The family is characterized by crowding of the flowers or florets into heads. It is cosmopolitan, and the plants show considerable variety in habit. The great majority, including most British representatives, are herbaceous, but in the warmer parts of the world shrubs and arborescent forms also occur. In herbaceous plants the leaves are often arranged in a rosette on a much shortened stem, as in dandelion, daisy and others; when the stem is elongated the leaves are generally alternate. The root is usually thickened, sometimes, as in dahlia, tuberous; root and stem contain oil passages, or, as in lettuce and dandelion, a milky white latex. The flower heads (*capitula*) are surrounded by an involucre of green bracts—these protect the head flowers in the bud stage, performing the usual function of a calyx. The enlarged top of the axis, the receptacle, is flat, convex or conical, and the flowers open in centripetal succession, from the margin to the centre of the head. In many cases, as in the sunflower or daisy, the outer or ray florets are larger and more conspicuous than the inner, or disk florets; in other cases, as in dandelion, the florets are all alike. Ray florets when present are usually pistillate, but neuter in some genera (as *Centaurea*); the disk florets are hermaphrodite. The flower is borne atop the ovary (epigynous); the calyx is sometimes absent, or is represented by a rim on the top of the ovary, or takes the form of hairs or bristles that enlarge in the fruiting stage to form the pappus, by means of which the seed is dispersed. The corolla, of five united petals, is regular and tubular in shape in the disk florets, or irregular, when it is either strap-shaped (ligulate), as in the ray florets of daisy, etc., and all the florets of dandelion, or more rarely two lipped. The five stamens are attached to the interior of the corolla tube; the filaments are free; the anthers are joined (syngenesious) to form a tube around the single style, ending in a

FIG. 2.—VERTICAL SECTION THROUGH THE FLOWER HEAD OF THE SUNFLOWER

pair of stigmas. The inferior ovary contains one ovule (attached to base of chamber), and ripens to form a dry one-seeded fruit, a typical achene; the seed is filled with the straight embryo.

The flower heads are an admirable example of an adaptation for pollination by insects. The crowding of the florets in heads ensures the pollination of a large number as the result of a single insect visit. Nectar is secreted at the base of the style, and is protected from rain or dew and the visits of short-lipped insects by the corolla tube, the length of which is correlated with the length of proboscis of the visiting insect. When the floret opens, the two stigmas are pressed together below the tube formed by the anthers, the latter split on the inside, and the pollen fills the tube; the style gradually lengthens and carries the pollen out of the anther tube, and finally the stigmas spread and expose the receptive surface, which has hitherto been hidden. Thus the flower is earlier a male and later a female. This favours cross-pollination as compared with self-pollination. In many cases there is a third stage, as in dandelion, where the stigmas finally curl back so that they touch any pollen grains that have been left on the style below, thus ensuring self-pollination if cross-pollination has not been effected.

Devices for distribution of the fruit are varied. Frequently there is a hairy or silky pappus, forming a tuft of hairs, as in thistle or coltsfoot, or a parachutelike structure, as in dandelion; these render the fruit sufficiently light to be carried by the wind. In *Bidens* the pappus consists of two or more stiff-barbed bristles by which the fruit clings to the coats of animals. Occasionally, as in sunflower or daisy, the fruits bear no special appendage and remain on the head until jerked off.

Composites are generally considered to represent the most highly developed family of flowering plants. As alluded to earlier, by the massing of the flowers in heads great economy is effected in the material required for one flower, as a large number of flowers are visited at one time by the pollinating insect.

A few members of the family are of economic value, e.g., *Lactuca* (lettuce), *Cichorium* (chicory), *Cynara* (artichoke and cardoon), *Helianthus* (Jerusalem artichoke). Many are cultivated as garden or greenhouse plants, such as *Solidago* (goldenrod), *Ageratum*, *Aster*, *Helichrysum* (everlasting), *Zinnia*, *Rudbeckia*, *Helianthus* (sunflower), *Coreopsis*, *Dahlia*, *Tagetes* (French and African marigold), *Gaillardia*, *Achillea* (yarrow), *Chrysanthemum*, *Tanacetum* (tansy), *Arnica*, *Doronicum*, *Cineraria*, *Calendula*, *Echinops* (globe thistle), *Centaurea*. Some are of medicinal value, such as *Anthemis* (camomile), *Artemisia* (wormwood), *Tussilago* (coltsfoot), *Arnica*. Insect powder is prepared from species of *Pyrethrum*

J. HORACE MCFARLAND CO.

FIG. 3.—BLUEBOTTLE OR CORNFLOWER (*CENTAUREA CYANUS*)

in the genus *Chrysanthemum*. A species of *Parthenium*, guayule, is a source of rubber.

The family is divided into two subfamilies: Tubuliflorae, characterized by absence of latex, and the florets of the disk being not ligulate, and Liguliflorae, characterized by the presence of latex and all the florets being ligulate. The first subfamily contains the majority of the genera, and is divided into a number of tribes.

The Compositae is well represented in Britain, in which about 40 genera are native. These include some of the commonest weeds, such as dandelion (*Taraxacum officinale*), daisy (*Bellis perennis*), groundsel (*Senecio vulgaris*) and ragwort (*S. jacobaea*); coltsfoot (*Tussilago farfara*) is one of the earliest plants to flower, and other genera are *Chrysanthemum* (oxeye daisy and corn marigold), *Arctium* (burdock), *Centaurea* (knapweed and cornflower), *Carduus* and *Cnicus* (thistles), *Hieracium* (hawkweed), *Sonchus* (sow thistle), *Achillea* (yarrow, or milfoil, and sneezewort), *Eupatorium* (hemp agrimony), *Gnaphalium* (cudweed), *Erigeron* (fleabane), *Solidago* (goldenrod), *Anthemis* (mayweed and camomile), *Cichorium* (chicory), *Lapsana* (nipplewort), *Crepis* (hawk's-beard), *Hypochaeris* (cat's-ear) and *Tragopogon* (goatsbeard).

See separate articles on the various composites; see also references under "Compositae" in the Index.

**COMPOSITE ORDER:** see, ORDER.

**COMPOUND**, a chemical substance that can be prepared by the combination of simpler substances or that can be resolved by ordinary chemical methods into simpler constituents, as opposed to a chemical element.

See ELEMENTS, CHEMICAL; MOLECULE.

**COMPRESSION.** This word is applied to many industrial processes, including the reduction in volume of air and gases for use or storage purposes, that of loose substances for convenience of transport, fluid compression in steel ingot making to drive out gases and produce sound steel, the testing of materials by forces tending to crush them and the production of gasoline from natural gas. In steam-engine cylinders the steam is compressed at the end of the stroke, to exert a cushioning effect and to prevent sudden shock to the parts at reversal. Higher speeds and smoother working are thus possible. Compression of the charge in a cylinder of an internal-combustion engine occurs preparatory to combustion. The fuel is ignited in the diesel engine by compressing the air so highly in the cylinders that ignition temperature is attained. See INTERNAL-COMBUSTION ENGINE; STEAM; see also references under "Compression" in the Index.

**COMPRESSOR**, a device for mechanically decreasing the volume of a gas or vapour by increasing its pressure. Although the most frequently compressed gas is air, others often compressed are the various refrigerants, natural gas, oxygen, nitrogen, carbon dioxide, hydrocarbons and numerous other gases of industrial importance. Compressors may be classified into three general types: positive displacement, centrifugal and axial. These types are discussed in order and are followed by discussion of efficiency, booster compressors and compressed air.

**Positive Displacement Compressors.**—Nearly all compressors in this category are of the reciprocating piston type in which the gas is compressed in a cylinder in the manner illustrated in fig. 1. After having compressed and delivered a charge of gas at the pressure  $P_2$  the piston is in the position represented by A in the diagram.

As it moves toward the right the air trapped in the clearance volume of the cylinder expands along the line AB. At B the pressure in the cylinder falls below that in the inlet line, forcing open the inlet valve. A new charge of air is thus drawn into the cylinder until the piston reaches the end of its stroke at point C. As the piston begins its return stroke the inlet valve is forced shut and the charge of air is compressed along the line CD. At the point D the pressure in the cylinder reaches a value sufficient to force the spring loaded discharge valve open, thus permitting the volume of air represented between points D and A to be discharged at the pressure  $P_2$ .

Compressors in which the entire pressure increase is accomplished in a single step as in fig. 1 are called single-stage compressors.

FIG. 1.—DIAGRAM SHOWING THE PRINCIPLE OF OPERATION OF A RECIPROCATING COMPRESSOR

sors. If a second stage of compression is employed, the discharge from the first-stage cylinder is delivered to the intake of a second-stage cylinder in which the gas is further compressed to a higher pressure. During the compression process the gas tends to increase in temperature so that some form of cooling is necessary. In small low-pressure designs, fins on the outside of the cylinders are sufficient. In larger compressors, water-jacketed cylinders are commonly employed. In two-stage machines, intercoolers may be used in which the air is reduced in temperature between stages by means of a water-cooled heat exchanger.

Reciprocating compressors are widely employed for the compression of air and refrigerant gases. They range in size from small single-cylinder units to large multicylinder installations capable of compressing thousands of cubic feet of gas per minute. Reciprocating compressors are the only type suited for compressing air and other gases to extremely high pressures.

**Centrifugal Compressors.**—Centrifugal compressors operate on the principle of increasing the kinetic energy of the gas with a high-speed impeller and subsequently converting this kinetic energy into increased pressure in a divergent outlet passage called the diffuser. The principle of operation of a centrifugal compressor is illustrated in fig. 2. Air enters the impeller eye with a low velocity and leaves the impeller at the periphery with a much higher velocity  $V$  which is the resultant of the tangential velocity  $V_t$  and the velocity of the impeller blade  $V_r$ . In the diffuser the velocity  $V$  is reduced to a low value at discharge causing the pres-

sure to rise by converting the kinetic energy of the gas into an increase in pressure.

The pressure increase obtainable depends upon the velocity with which the air leaves the tip of the impeller blades. This in turn is limited by the centrifugal force that the blades can safely stand. Another factor influencing the pressure rise is the density of the gas. In general the increase obtainable is proportional to the density, making the heavier gases more suitable for centrifugal compression, especially if high-pressure ratios are desired.

Centrifugal compressors are particularly suited to the compression of large volumes of gas to moderate pressures. Such compressors are widely employed for the compression of Freon refrigerant vapours in large refrigeration and air-conditioning installations. They have also been used in stationary gas turbines as well as in jet engines. In the latter application the centrifugal compressor has the disadvantage of offering a larger frontal area than does the axial compressor (see below) and has therefore been largely abandoned for that application. However, some of the earlier jet engines employed compressors of this type.

**Axial Compressors.**—This design derives its name from the fact that the flow through the compressor is in the axial direction; that is, parallel to the axis of rotation as in a common household fan. Axial-flow compressors differ from fans in that they are designed to increase the pressure of the gas by a substantial amount whereas fans are usually employed simply to move air. The most common application of axial compressors is in jet aircraft engines and in gas turbines.

The basic principle of operation of the axial-flow compressor

FIG. 3.—CROSS SECTION OF AN AXIAL-FLOW COMPRESSOR

is alternately to increase and decrease the velocity of the gas flowing through the compressor. During each increase in velocity the kinetic energy of the gas is increased and during each decrease in velocity this kinetic energy is converted into an increase in pressure.

The process is accomplished by means of a large drum-type rotor having many rows of aerodynamically shaped blades extending outward from it in a radial direction. This rotor is surrounded by a stationary casing, which also contains a similar number of rows of blades that extend inward and fit between the rows of blades on the rotor.

When assembled the two halves of the casing fit together around the rotor to form an annular passage into which the blades extend and through which the gas flows as it is compressed. A cross-sectional drawing of a typical axial compressor is illustrated in fig. 3.

Various blade designs accomplish different objectives with respect to the flow pattern through the compressor. A typical one that will illustrate the principle of operation of axial compressors is represented in fig. 4. The row of moving blades attached

FIG. 2.—DIAGRAM OF IMPELLER, DIFFUSER AND CASING FOR A CENTRIFUGAL COMPRESSOR

to the rotor and the row of stationary blades attached to the casing may be taken as typical for a single stage of compression. The moving blades travel to the right with the velocity  $V_b$  and the entering gas travels in the direction shown with the velocity  $V_1$ . The moving blades catch this entering gas and give it a whirl in the direction of rotation so that it leaves the moving blades with a relative velocity  $V_{r2}$  but with an actual velocity relative to the next row of stationary blades equal to  $V_2$ . Thus, in passing through the moving row of blades the gas has been given an increase in velocity from  $V_1$  to  $V_2$ . This requires an addition of energy to the rotor that must be supplied by some outside source such as an electric motor or turbine. The gas with the velocity  $V_2$  next enters the stationary row of blades. In passing through these the gas is turned somewhat in the axial direction and leaves the stationary blades with the velocity  $V_1$ . In passing through the stationary blades, therefore, the gas has suffered a decrease in velocity from  $V_2$  to  $V_1$ . This results in the desired increase in pressure across the stage. Since the velocity change is small the pressure rise is also small. By employing a number of stages in series, however, the desired over-all pressure increase can be obtained.

As already indicated this type of compressor is used principally for jet aircraft engines and gas turbines. For a discussion of the role of the compressor in jet engines and gas turbines, see **TURBINE**.

**Efficiency of Compressors.**—The efficiency of compressors is defined as the ratio of the work required to compress the gas isentropically, i.e., at constant entropy, to the work actually delivered to the rotor, impeller or crankshaft. In well-designed axial and centrifugal compressors this ranges between 0.80 and 0.90 with typical values being approximately 0.85. About the same efficiency may be expected with large reciprocating machines.

**Booster Compressors.**—In the transportation of natural gas by pipeline, booster compressor stations are employed at regular intervals along the lines in order to restore pressure loss between stations. These compressors are high-capacity, low-pressure ratio machines of either the centrifugal or reciprocating type. They may be driven in a number of ways; with gas engines, gas turbines, steam turbines or electric motors. The pressure in the pipelines is usually maintained between about 500 and 1,200 lb. per square inch. Pressure ratios across the machines may be anywhere from about 1.1 to 1.8 depending on the distance between stations and other factors.

**Compressed Air.**—No other power agent with the possible exception of electricity has such a varied range of uses as compressed air. In the category of free action it is employed in jets of all kinds, such as, for example, sand-blasting, the cleaning of machinery and fabrics, the spraying of paints and other similar applications. There also are numerous methods in which air, expanding in a cylinder or small turbine, can be used for operating portable pneumatic tools and other devices. In addition, compressed air is used for brakes on trains and heavy vehicles, for pressurizing aircraft passenger compartments, for the operation of hoists and in many thousands of filling stations and garages for the inflation of tires and other applications.

**COMPROMISE OF 1850**, a term referring to the series of five measures passed by the U.S. congress in Sept. 1850 in an effort to settle outstanding issues involving slavery and to avert the threat of disunion.

When the 31st congress met on Dec. 3, 1849, it was faced with a request from California for admission to the union with a constitution excluding slavery. The question of the extension of slavery into the territory ceded by Mexico in 1848 had created severe tension, both in congress and in the country generally. The request of California compelled congress to take a stand on the larger question, for failure to admit California with the constitution of its own choice would certainly have led to separatist movements on the west coast. Northern antislavery groups supported California vigorously, but southern leaders generally were as determined in their opposition, partly because the admission of California would upset the traditional numerical balance between free and slave states. (There were then 15 slave states and 15 free states.) This southern opposition became more determined when Pres. Zachary Taylor, himself a slaveholder, unexpectedly supported California and gave some encouragement to a move to establish a free state in New Mexico. Southern extremists countered by calling a convention of the southern states to meet in Nashville, Tenn., in June 1850, to discuss ways of defending southern interests against what they asserted was a continuing denial of justice to their section. It appeared that only some compromise acceptable to moderates in all sections could prevent a sectional schism.

At the close of Jan. 1850, Sen. Henry Clay of Kentucky had initiated the first major effort at compromise when he introduced five bills which, he hoped, would give some satisfaction to both the slavery and the antislavery groups. These bills provided for the admission of California with the constitution it had already adopted, the organization of the remaining part of the Mexican cession into the territories of New Mexico and Utah without any provision concerning slavery, a new and more rigorous law for the return of fugitive slaves, the prohibition of the slave trade in the District of Columbia, and the assignment to New Mexico of the territory in dispute with Texas, giving the latter compensation in the form of the assumption by the federal government of Texan debts to the amount of \$10,000,000.

These proposals precipitated one of the great senate debates of the 19th century. Clay, Thomas Hart Benton of Missouri, Daniel Webster of Massachusetts and John C. Calhoun of South Carolina were among the participants. Webster supported Clay, arguing that legislation offensive to the south was unnecessary because slavery could not prosper in the territories of the far west. Calhoun defended the extreme southern position, alleging that the northern majority was systematically infringing the rights of his section. A younger senator, William H. Seward of New York, presented the antislavery position in asserting that there was a moral law more sacred than the constitution. The measures were referred to a special committee, which reported them as a single bill, known as the omnibus bill. It was defeated, however, partly because it was opposed by President Taylor, who declared that the admission of California should not be contingent upon action on any other measure. The crisis had reached an ominous impasse.

On July 9, President Taylor died after a brief illness. His successor, Millard Fillmore, favoured the compromise proposals. The five measures included in the omnibus bill were brought forward by Stephen A. Douglas of Illinois, and after a brief debate they were passed by the senate as separate bills. Before the end of September they had passed the house of representatives and had become law.

The outcome was accepted by moderates in all sections, and the secession of the southern states had been postponed for a decade. The compromise, however, contained the seeds of future discord. The opening of New Mexico and Utah to slavery led to the de-

mand, in 1854, for similar action in Kansas, while the new fugitive slave law contained provisions so obnoxious to moderate anti-slavery elements that they became determined opponents of any further extension of the area open to slavery. By its very nature, the compromise could be only a temporary expedient. See also UNITED STATES (OF AMERICA): *History*, (H. W. By.)

**COMPTON, ARTHUR HOLLY** (1892–1962), U.S. physicist who in 1923 discovered the change in the wave length of X-rays when scattered by matter, the phenomenon known as the Compton effect (*q.v.*). He was born in Wooster, O., Sept. 10, 1892. In recognition of his achievements in research he was awarded in 1927, jointly with C. T. R. Wilson of England, the Nobel prize for physics. From 1942 to 1945 he served as director of the metallurgical laboratory at The University of Chicago which developed the first self-sustaining atomic chain reaction, paving the way for the controlled release of nuclear energy.

He was educated at the College of Wooster (Wooster, O.) and at Princeton university where he received his Ph.D. in 1916. Following teaching and industrial research experience and a year of advanced study in England, he was made professor and head of the department of physics at Washington university, St. Louis, Mo. In 1923 he was appointed professor of physics at The University of Chicago and later served as chairman of the department of physics and dean of the division of the physical sciences. He returned to Washington university as chancellor in 1945 and served until 1953, at which time he became distinguished service professor of natural philosophy. He resigned this post in 1961 and died at Berkeley, Calif., on March 15, 1962.

In addition to many scientific articles Compton wrote *Secondary Radiations Produced by X-rays* (1922), *X-rays and Electrons* (1926), *Freedom of Man* (1935), *X-rays in Theory and Experiment* (with S. K. Allison, 1935), *Human Meaning of Science* (1940) and *Atomic Quest* (1956). (E. T. F.)

**COMPTON, HENRY** (1632–1713), bishop of London who played a leading part in English politics during the crisis of James II's reign, was born at Compton Wynyates, Warwickshire, and educated at Queen's college, Oxford. Ordained in 1666, he became bishop of Oxford in 1674 and of London in 1675. His staunch Protestantism brought him into disfavour with James II, who in 1685 deprived him of his seat in the privy council. Next year, for refusing to suspend John Sharp, rector of St. Giles-in-the-Fields, whose antipapal sermons had offended the king, Compton was himself suspended. He gave his support to the seven bishops who made a petition against the king's Declaration of Indulgence (1687) and was the only ecclesiastic to sign the invitation to William of Orange to come to England. When John Tillotson was preferred to him as archbishop of Canterbury (1691), Compton therefore suffered a bitter disappointment. Under Queen Anne, Compton gave full support to the Tories, and Francis Atterbury, bishop of Rochester, was his protégé. As bishop of London Compton gave every encouragement to the newly founded Society for the Propagation of the Gospel and to missionary work in America. He died at Fulham, July 7, 1713.

See E. F. Carpenter, *The Protestant Bishop* (1956). (G. Hu.)

**COMPTON EFFECT**, the increase in wave length, or the reduction in frequency, of X-rays and gamma rays that have been scattered by electrons. This change in quality of the radiation depends markedly on the angle through which the rays are scattered, the change being greater for larger angles. When discovered by Arthur H. Compton in 1923, this phenomenon posed crucial problems for physics. The explanation provided by Compton required that radiation have a corpuscular nature in which each quantum or photon carries directed momentum as well as energy. However, these corpuscular properties of radiation were entirely inconsistent with its long-established wave properties, and to preserve these physicists wondered whether the Compton effect might not require the abandonment of the basic laws of conservation of energy and momentum in atomic processes. However, with the discovery and development of quantum mechanics (*q.v.*) it was shown that not only radiation, but matter as well, possesses both wave and corpuscular properties, and thus the Compton effect became one of the basic phenomena of physics.

**Discovery of Compton Effect.**—Soon after the discovery of X-rays (*q.v.*) by W. C. Röntgen it was realized that this radiation would be a powerful source for investigating the nature of matter. One of the most important uses was found by J. J. Thomson, who investigated the process of X-ray scattering by matter on the theory that electrons bound in atoms oscillate under the action of the X-rays and thus reradiate energy. In this process X-rays are scattered without change in wave length or frequency exactly as visible light is scattered by the earth's atmosphere. However, in 1912, C. A. Sadler and P. Mesham conducted scattering experiments with X-rays of short wave length produced by X-ray tubes operated at high voltages, and showed that these X-rays after being scattered by light elements are of longer wave length than before being scattered. Similar results were found in 1920 by J. A. Gray for scattered gamma rays. Gray also found that the increase in wave length of the scattered gamma rays, as revealed by their greater absorption, increases with the angle of scattering. Compton had also observed the increased wave length of scattered gamma rays in experiments conducted at Cambridge university as early as 1919, and continued a systematic investigation of the phenomenon.

In 1923 Compton published a full discussion of the secondary radiations produced by X-rays, including the changes produced by X-rays by scattering. At the same time he proposed an entirely new theoretical explanation, suggesting that when an X-ray is scattered, it shares its energy and momentum with a single electron. See ELECTRON.

**Photons and Recoil Electrons.**—The Compton theory of X-ray scattering considered X-rays to be corpuscular photons or quanta similar to those introduced by Einstein in 1905 to explain the photoelectric effect (see PHOTOELECTRICITY). The important new idea introduced by Compton was that momentum as well as energy must be considered as being carried by individual corpuscles, or photons, of radiation. The Compton theory of X-ray scattering from electrons predicted the reduced frequency of the scattered radiation, and explained it as being caused by electrons whose recoil took up the difference in energy and momentum between incident and scattered X-ray photons. This effect became increasingly prominent as the frequency of the X-rays is increased and is most clearly evident with scatterers of low atomic number in which the electrons are loosely bound. The Compton theory of X-ray scattering was one of the first atomic theories to take account of the theory of relativity.

In 1923 Compton made accurate spectrographic measurements of the X-ray scattering through an angle  $\phi$  from carbon, with the apparatus shown in fig. 1. He employed a Bragg X-ray diffraction spectrometer for precise wave-length determinations and showed that the scattered X-rays contain radiations of two kinds: the Thomson type radiation with wave length identical to that in the incident X-ray beam and, of far greater significance, modified X-rays with longer wave lengths.

The wave length of this latter type radiation differs from that of the incident X-rays by an amount depending on the angle of scattering  $\phi$  in precisely the way predicted by the Compton theory.

$$\lambda' - \lambda = \frac{h}{mc} (1 - \cos \phi)$$

Here  $\lambda$  is the wave length of the incident X-rays,  $\lambda'$  that of the rays scattered through the angle  $\phi$ ,  $h$  is Planck's constant,  $m$  the electron mass and  $c$  the speed of light. Fig. 2 shows the measurements made by Compton in 1923 of the change in wave length when X-rays are scattered at several different angles. The apparatus used was that shown in fig. 1.

The Compton corpuscular theory of X-ray scattering also predicted that the electrons responsible for the scattering must recoil with the energy and momentum necessary to balance the scattering event. The energy thus gained by an electron recoiling at an angle  $\theta$  is

$$E = \frac{hc}{\lambda} \frac{2\alpha \cos^2 \theta}{(1 + \alpha)^2 - \alpha^2 \cos^2 \theta}, \text{ where } \alpha = \frac{h}{\lambda mc}$$

Such recoil electrons were observed in cloud-chamber photographs

taken by C. T. R. Wilson at Cambridge, Eng., in 1923, and their observed energies were shown by Compton and J. C. Hubbard to be consistent with the established theory.

As soon as the basic phenomena of the Compton effect were established, they raised very serious problems concerning the foundations of atomic physics. Since the Compton theory explained the phenomena by wholly corpuscular properties of radiation and electrons, it first seemed that either the wave theory of light or the basic principles of conservation of energy and momentum in individual scattering events must be abandoned. In an effort to reconcile the wave nature of X-rays with the Compton effect, N. Bohr, H. A. Kramers and J. C. Slater proposed in 1924 a statistical theory for the phenomenon. In this they abandoned the conservation of energy and momentum for individual scattering events between X-rays and electrons, and considered these conservation laws as holding only for the statistical average of a large number of such interactions. This compromise was not needed, for in the years following its discovery, the Compton effect proved to be one of the most important cornerstones of quantum mechanics, which requires both wave and corpuscular properties for matter as well as for radiation.

**Simultaneity.**—A crucial experimental test was soon proposed for deciding between the Bohr, Kramers and Slater view and the Compton scattering theory. A basic requirement of the Compton theory is that the scattered X-ray photon and recoil electron should appear at the same instant of time, while according to the Bohr, Kramers and Slater hypothesis, these events would occur at random. An experiment using two Geiger counters was carried out in 1925 by W. Böthe and H. Geiger; this demonstrated that in many cases the scattered photon which actuated one counter and the recoil electron which discharged the other counter appeared within  $10^{-2}$  sec. of each other. Although this is not high resolution, it was nevertheless concluded that the number of such coincidences observed was very much larger than the number which could be expected on a purely random basis. The Bothe-Geiger type of experiment has been repeated by several experimenters, and any possible time interval between the appearance of recoil electron and scattered photon has been steadily reduced. In 1936 R. S. Shankland showed that this time interval is less than  $10^{-6}$  sec., a result also found in experiments by W. E. Burcham and W. B. Lewis. Much faster electronic techniques and scintillation counters were available by 1950, and they were employed by R. Hofstadter and J. A. McIntyre to show that any possible time lag is less than  $10^{-8}$  sec.; in 1952 R. E. Bell further reduced the interval to  $10^{-10}$  sec. By the mid-1950s there was not the slightest doubt regarding this aspect of the Compton theory. It should be

mentioned that the quantum theory of Compton scattering permits a time lag of about  $10^{-10}$  sec., an interval far shorter than any possible experimental observation.

**Conservation of Energy and Momentum.**—A much more stringent test for the quantum theory of the Compton effect is to observe the angles at which recoil electron and scattered photon pairs travel out from the point of scattering. The Compton theory predicts that

$$\cot \theta = -(1 + a) \tan \frac{\phi}{2}$$

This angular relationship as shown in fig. 3 was first tested by Compton and A. W. Simon in cloud-chamber observations of the scattering of high-energy X-rays. They could establish the initial direction of motion of the recoil electron track and in certain cases found at another point in the cloud chamber the track of a second electron ejected from an atom by the scattered X-ray photon. The momentum vectors for the incident X-ray photon, the scattered X-ray photon and the recoil electron satisfied the conservation laws for energy and momentum. The number of cases in which these related pairs of electrons were observed at the expected angles was not large, but seemed sufficient to confirm the theoretical predictions.

A test of both the angular relationship and the time coincidence was made by Shankland in 1936. These experiments employed Geiger counters placed at the predicted angles  $\phi$  and  $\theta$  of fig. 3, in a circuit which recorded time coincidences between the counter discharges. The observations proved that the angular relationship is confirmed to an accuracy of  $\pm 10^\circ$ , and that no time lag as great as  $10^{-6}$  sec. occurs between the counter discharges. Similar experiments giving confirmation of both the angular relationship and simultaneity were performed by J. C. Jacobson, by G. Bernardini and S. Franchetti, and by W. Bothe and H. Maier-Leibnitz. In 1950 W. G. Cross and N. F. Ramsey, using the much faster coincidence counting methods and more efficient scintillation detectors then available, confirmed the angular relationship to within  $\pm 1^\circ$ , and reduced any possible time lag to  $10^{-8}$  sec. They also confirmed that the three vectors shown in fig. 3 are in the same plane, as they must be for momentum to be conserved. Fig. 4 shows the apparatus used by Cross and Ramsey in these experiments, in which gamma rays are scattered by electrons in a beryllium foil. The electrons recoiling to the electron counter are accompanied by modified gamma rays traveling to the gamma ray counter. The recoil electron and scattered photon pairs discharge these counters simultaneously when the counters are set at the angles predicted by the Compton theory. The experimental proof of the angular predictions of the Compton theory and of simultaneity in the scattering events is a conclusive proof that both energy and momentum are conserved in individual Compton scattering events between X-rays and electrons. These results constituted an essential step beyond the mere demonstration of simultaneity as provided by the Bothe-Geiger type of experiment.

FIG. 2.—X-RAY SPECTRA OBTAINED BY A. H. COMPTON WITH THE APPARATUS SHOWN IN FIG. 1, PROVING THE PROGRESSIVE CHANGE IN WAVELENGTH OF THE COMPTON MODIFIED LINE  $M$  FOR VARIOUS SCATTERING ANGLES  $\phi$ .  $P$  INDICATES THE UNMODIFIED SCATTERED LINE.

FIG. 1.—APPARATUS USED BY A. H. COMPTON IN 1923 TO PROVE THAT X-RAYS OF A SINGLE WAVELENGTH SCATTERED THROUGH AN ANGLE  $\phi$  FROM GRAPHITE SCATTERER  $R$  CONTAIN A MODIFIED COMPONENT AT A LONGER WAVELENGTH AS ANALYZED BY A BRAGG X-RAY CRYSTAL SPECTROMETER.

### Compton Effect and Relativistic Quantum Mechanics.—

The development of relativistic quantum mechanics by P. A. M. Dirac in 1928 made possible a very basic description and explanation of the Compton effect. While the original corpuscular theory of the Compton effect gave great impetus to the development of quantum theory, and in particular to the view that radiation travels in directed photons having discrete energy and momentum, it had at the same time raised serious questions about the seemingly well-established wave nature of light. However, relativistic quantum mechanics gives a general description of Compton scattering in terms of the dual wave-corpuscle nature of both radiation and electrons. The Dirac theory of the Compton effect predicts results

FIG. 3.—COMPTON EFFECT (see TEXT)

identical with those of the early corpuscular theory as regards change in wave length with scattering angle, energy of the recoil electrons, simultaneity and the angular relationship between recoil electron and scattered photon. In addition it predicts the intensity of scattered X-rays as a function of scattering angle, a result which has been confirmed by experiment and which was not correctly given by the earlier theory.

This situation arises from the fact that Dirac's relativistic quantum theory of the electron incorporates a most unusual feature in its prediction of negative energy states for electrons. Although the reality of these negative energy states was later confirmed by the discovery of the positron (see PARTICLES, ELEMENTARY), the Compton effect provided the first crucial test for the negative energy states. The theoretical prediction was incorporated in a formula for the intensity of Compton-scattered X-rays as derived by O. Klein and Y. Nishina using the Dirac theory. The photon scattering is a second-order process described in the theory by assuming that the primary photon is first absorbed by the electron, leaving the latter in an intermediate state, and then when the photon is actually scattered, its emission leaves the electron in a final energy state. The essential point, however, is that the intermediate states can include those in which the electron has negative energy, and the contribution of these states to the total scattering of photons by the Compton process is essential. Of course, both before and after scattering a photon, the electron is in states of positive energy, but intermediate states of either positive or negative energy are possible. Experiments designed to test this point were in close agreement with the predictions of the Klein-Nishina formula and thus proved decisively the reality of Dirac's negative energy states for the electron, a theory now basic for the understanding of the properties of all elementary particles.

By the mid-1950s all aspects of the Compton-Dirac theory had been accurately confirmed by numerous experiments using X-rays and gamma rays over an extremely wide energy range. Compton's original data on the intensity of gamma-ray scattering at various

angles obtained at Cambridge university in 1919 were explained, and the 1950 precision experiments of Hofstadter and McIntyre proved to be in excellent agreement with theory. Other important intensity measurements include those of W. H. Voelker in 1952 using 15-Mev (million electron volts) gamma rays from a beta-tron, and measurements by F. H. Coensgen made with the Berkeley electron-synchrotron operating at 250 Mev. The confirmation of Compton's theory of scattering at the highest X-ray energies provided a sensitive and important test for the understanding of the interaction of radiation with matter.

Although the usual Compton event results in a single scattered photon, it is also possible on rare occasions for two scattered photons to appear. The occurrence of this double Compton effect was also predicted by relativistic quantum mechanics, and experiments provide confirmation of the predicted details of this process.

The Compton effect occupies a position of primary importance in the development of physics in the 20th century, first, because at the outset it stimulated the development of quantum mechanics by providing very basic experimental findings which classical theories were powerless to explain; moreover, during the entire development of quantum mechanics, the Compton effect has been one of the central phenomena with which the theory could be tested by experiment at many crucial points. It is probable that in the near future it will provide another decisive test for one of the basic facts of quantum electrodynamics related to ultra-high-energy phenomena (see QUANTUM MECHANICS: *Quantum Electrodynamics*). It is expected that at very high energies modification of the theory may be necessary. This involves the question of a fundamental length in the interactions of elementary particles which is presumably the smallest length that can be measured. If this length is found to be a fundamental feature in nature, it is probable that its existence will be established by observations on the Compton effect in the scattering of very high energy photons. It would be revealed by departures from predictions of the present theory of quantum electrodynamics in the energy range above  $10^{12}$  electron volts. Thus, the Compton effect may again help point the way for new developments in theoretical physics.

(1954); R. S. Shankland, *Atomic and Nuclear Physics*, 2nd ed. (1960); E. T. Whittaker, *A History of the Theories of Aether and Electricity*, vol. II (R. S. So.) (1953).

**COMPTROLLER (CONTROLLER)**, the title sometimes given to the official whose primary responsibility is to furnish an organization with accounting records and reports. He is responsible for instituting and maintaining documents and records for safeguarding assets, disclosing liabilities, presenting income and other tax information, and preparing and interpreting operating and financial reports.

The controller of a private business organization often has important advisory functions in addition to the record-keeping and reporting responsibilities of the earlier chief accountant. A controller helps prepare and enforce the budget, measure expected profitability of alternate proposals, and assemble relevant information for administrative decision making. In short, he is responsible for accumulating and interpreting information and for translating it into instruments of administrative control.

The controller usually maintains procedures for auditing invoices, vouchers, plant records, warrants and payrolls. These and other auditing procedures are sometimes centralized under an internal auditor who may be responsible to the controller, to the president of the company or to the board of directors. Controllership functions are occasionally distributed among different officials and the title of controller is then omitted. The controller should be sharply distinguished from the treasurer, property custodian and others who handle the physical assets of the organization.

Units of government traditionally give greater emphasis to auditing and safeguarding features and less emphasis to advisory functions. Branches of the U.S. government make use of numerous controllers including the comptroller of the currency, an office created by the National Bank act of 1863 to supervise all national

FIG. 4.—EXPERIMENT TO PROVE THE LAWS OF CONSERVATION OF ENERGY AND MOMENTUM IN INDIVIDUAL COMPTON SCATTERING EVENTS

banks and approve the creation of new national banks. The British government has an official designated as the comptroller and auditor general. He holds a permanent appointment as an officer of parliament and is responsible for ensuring that all government expenditures are properly made. (C. T. D.)

**COMPUTER.** Electronic computers, which were first used in the 1940s in a few research laboratories, have now become commonplace tools in data processing for government, business, and industry; in scheduling and control of manufacturing operations; in medical analyses; in transportation and communication systems; in military systems of all types; and in scientific activities. Manufacture of computers has reached the status of a major industry, and a whole new profession has arisen—the art of using and applying computers to problems of all types. Many colleges and universities now offer some instruction in the design or use of computers, and science and mathematics curricula are being revised in the secondary (and even in the elementary) schools to introduce the new concepts required. Perhaps no other single development has had such an impact on human endeavours in such a brief period of time, and it is probable that in the future computers will affect the lives of everyone in some way. For INFORMATION PROCESSING, which has been profoundly influenced by computer technology, see the general article under that title.

**Classes of Computers.**—Electronic computers can be broadly divided into two classes, analogue (or analog) and digital. In the former, a variable quantity that is to be studied or manipulated is represented by an electrical quantity, usually an electrical potential. The machine quantities are said to be analogous to the actual quantities—hence the name “analogue.” In the digital computer, the variable quantities are represented by numerical codes, usually in the binary number system. The two classes of computers use such different techniques and are put to such different uses that they will be treated separately. First, however, it will be well to compare the techniques and point out the advantages and disadvantages of each.

**Accuracy.**—Since an analogue computer represents or simulates quantities with electrical potentials whose values are proportional to the quantities represented, its accuracy is limited by such practical circuit problems as linearity of amplifiers, stability of the value of circuit components, background noise that changes with time, etc. Stability of the value of the circuit components has a direct effect on output; a change of 1% in the value of the output resistor of a multiplier will change the multiplying factor by 1%. For many applications an accuracy of 1% is adequate and can be easily obtained. If, however, a number of operations have to be cascaded, an acceptable overall accuracy may require a much better accuracy in each stage; this is particularly so if one of the operations involves the subtraction of one quantity from another almost equal to it. (For instance, if a quantity of 19 units is subtracted from another of 20 units, then an accuracy of 1% in the difference requires an accuracy of 0.05% in each of the quantities.) Accuracies of 0.1% can be obtained without much difficulty, but to get and maintain accuracies much better than this requires careful design and very good components. In a digital computer, on the other hand, the numerical codes that represent quantities require only the reliable recognition of two states of a circuit or device, as will be discussed below. Wide tolerances (up to 20%) can be placed on individual components without causing errors. Also, since the numerical codes can be made as large as desired, the accuracy in calculations is virtually unlimited.

**Speed.**—For certain problems, analogue computers can be faster than digital computers. This is because a digital computer, despite its very high speed of performing individual operations, must proceed one step at a time. In an analogue computer, a separate computing element is provided for each operation, and all are at work simultaneously and continuously.

**Hybrid Techniques.**—Since each type of computer has limitations as well as advantages, there is a growing interest in hybrid techniques, partly analogue, partly digital. In many applications, hybrid techniques have been able to exploit the best features of both classes and yield a better result (faster computation with a given accuracy level, less equipment, or some other criteria)

than either the completely analogue or the completely digital techniques.

## ANALOGUE COMPUTERS

As mentioned above, most analogue computers operate by manipulating electrical potentials, or, more usually, potential differences. The basic unit of an analogue computer is the operational amplifier, which is a device whose output current is proportional to its input potential difference. By causing this output current to flow through suitable components, further potential differences are obtained that can be made to bear any one of a wide range of relationships to the input.

If the input is applied to such an amplifier and the output circuit consists of a resistor, the potential difference across this resistor will be proportional to the output current and hence to the input potential difference. The amplifier will therefore act as a multiplier, the multiplying factor being proportional to the value of the output resistor, which can be varied over a wide range. If a number of such amplifiers are connected with their outputs in parallel, the current through the common resistor will be the sum of all the individual output currents and will be proportional to the sum of the individual input potential differences. The amplifier will therefore behave as an adder. If the output current is caused to flow into a capacitor, a charge will build up that is proportional to the product of the current and the time during which it flows; in this case the amplifier will act as an integrator.

By various circuit artifices, a wide variety of mathematical operations can be carried out on the potential differences. Since the output of each of these amplifying stages is also a potential difference and can be made of the same order of magnitude as the input, it can therefore serve as an input to a further operational stage. Most practical analogue computers consist of a number of such operational units, which can be connected so as to build up a mathematical expression, sometimes of great complexity and with many variables.

Although these amplifiers generally operate at frequencies up to 10,000 cycles per second, they must retain amplification at zero frequency in order to handle the constant terms of the inputs. Analogue computers may be used to simulate time-varying quantities, either in “real time” (a speed sufficient to provide an answer to a problem within the actual time it must be solved) or at a greater speed than in actuality, the latter being limited by the high-frequency cutoff of the amplifiers. Until the late 1950s, all electrical analogue computers used vacuum tubes, but newer designs, using transistors, are much smaller, consume less power, and are less expensive. In the mid-1960s desk-top units with 40–80 operation amplifiers cost from \$20,000 to \$50,000, and large installations sometimes exceeded \$500,000.

**Applications.**—The original electronic analogue computers arose from the needs of antiaircraft artillery “predictors.” In these, the variables were the latitude, longitude, and height of the target and the projectile respectively, all of these varying with another variable, time. A number of fixed or slowly varying data were also fed into the predictor, such as the muzzle velocity and ballistic characteristics of the projectile, the characteristics of the atmosphere, etc.; the computer had to solve two simultaneous equations so that the target and the projectile, each moving along its own course, would arrive at the point of intersection at the same time.

One interesting application of analogue computers is in aerodynamics. The equations relating air flow and the attitude of, and forces on, the lifting surfaces are complex, and their solutions by conventional methods were so difficult and tedious that many designers preferred to ignore theory and rely on experiment. Analogue computers became available at a time when the experimental approach was becoming impossibly expensive and dangerous, and difficult equations involving such problems as flutter are now within their capability.

The following application illustrates how these machines can be used as an experimental tool. An aerodynamicist may from prior experience, from simple theory, or even from intuition have a rough idea of the relationship between the various quantities in-

volved; he can set up the relationship on an analogue computer and can produce curves giving the variation of lift (for example) with any combination of the other variables. He now seeks experimental data for some of these combinations and compares these experimental results with those of his computer; if his original assumptions were not correct, his experimental results will not "fit." He next varies his original assumptions, repeating his attempt to fit his experimental points to the computed curves. As this fit improves, the equations set up in the computer are more and more descriptive of the true relationship between the variables. As this relationship is thus more accurately reproduced, it can be used to replace the original assumed relationships, and the aerodynamicist can confidently use his computer for other combinations of variables.

Such a computer can so completely describe the relationships of speed, attitude, lift, etc., of an aircraft that it can simulate the complete behaviour of an actual aircraft. If the multiplying, integrating, and other factors of the various units are brought out to controls similar to aircraft controls, and the outputs to suitable actuators, a pupil can be made to experience all the operations of flying an aircraft; with such a "simulator" he can be taught all that he needs to know to fly the aircraft under normal, faulty, or even emergency conditions without the expense and danger of learning by actually flying.

**General- and Special-Purpose Machines.**—Many analogue computers are general-purpose machines, adapted for solving a wide range of problems. There are, however, many special-purpose analogue computers merging into types that carry out functions similar to those of normal analogue computers but which are not considered to be computers at all. Examples are process controllers in chemical manufacturing plants and automatic pilots in aircraft. In such special-purpose machines, the outputs of transducers operated by physical parameters (temperature, fluid flow, pressure, etc., in the chemical example; aircraft attitude, speed, altitude, etc., in the automatic-pilot example) are fed into a device that combines them by arithmetical processes effected by methods commonly used in analogue computers.

### DIGITAL COMPUTERS

The familiar office adding machines and desk calculators are rudimentary examples of digital computers in that they work with numerical representations of quantities that are to be manipulated. The three distinguishing characteristics of the modern digital computer are (1) an addressable memory to hold a stored sequence of operations to be carried out automatically (a program), the necessary data, and intermediate results; (2) the concept of logical decision making, *i.e.*, the ability to automatically take specified alternate courses of action depending on the outcome of a particular operation; and (3) extremely high speed, up to 1,000,000 or more operations per second. Actually, a man with a desk calculator, using pencil and paper for memory and tables for data, could carry out the same sequence of operations as that performed by an electronic digital computer on a particular problem, make the same decisions, and find the same answers. Because of the great difference in speed, however, it would take him several years to do what the electronic digital computer can do in a matter of minutes. Similarly, a digital computer can rapidly find a desired item out of many millions of items stored in its memory, update it, refile it, etc., vastly speeding up routine clerical tasks in such fields as banking, insurance records, and airline reservations.

The functional elements of the digital computer may be grouped into four major categories: (1) the arithmetical unit, which performs tasks such as addition, multiplication, logical comparison, etc.; (2) the memory, in which data words and sequences of instructions are stored; (3) the input-output system, which permits the entry of programs and data and the output of results; and (4) the instruction control unit, which interprets the sequence of operations (program) stored in the memory and controls the other functional units appropriately. Digital computers are constructed in a wide range of sizes, with prices in the mid-1960s ranging from about \$20,000 for desk-top units to \$10,000,000 for

large computers that fill a large room. Despite this wide range in size and cost, all digital computers have the same functional elements; the cost and size differences come in the degree of sophistication employed and in the size of the problems to be solved or the files to be maintained. For example, the arithmetic unit of a small computer may be capable of performing only a few simple operations, such as adding and shifting numbers. More complex operations, such as multiplication and division, can be performed on such machines by programming sequences of these basic operations, but such programmed operations are slow and take up valuable memory space. The larger machines provide more "built-in" automatic operations, such as multiplication and division, to save time and reduce the memory space needed for programs. Similarly, the amount and type of memory employed are chosen to meet the needs of the intended usage, as are the characteristics of the input-output devices.

**Binary Code.**—Most digital computers use the binary code, which has only two digits, 0 and 1, and which can be represented electrically by a variety of two-state (switching) devices; a switch can be "on" for 1 and "off" for 0. It is much easier to design two-state devices than the ten-state devices that would be required for decimal code. Also, the arithmetical processes are much simpler in binary code than in decimal code. In the normal decimal notation, each digit represents successive powers of ten. Thus the number 251 means  $2 \times 10^2 + 5 \times 10 + 1$ ; the corresponding binary code for this number is 1111011, meaning  $2^7 + 2^6 + 2^5 + 2^4 + 2^3 + 2 + 1$ . The binary equivalents of some decimal integers are written as follows:

1	1
2	10
3	11
4	100
5	101
6	110
7	111
8	1000
9	1001
10	1010
20	10100
100	1100100

In normal decimal numbers, multiplication by ten is performed by shifting the number one place to the left and adding a zero; the above list shows that in binary arithmetic this operation results in a multiplication by two. The list also shows that binary numbers have more, sometimes many more, digits than the corresponding decimal numbers; the binary number for 100 has the same number of digits as the decimal number for 1,000,000. The most common number length in binary machines is 36 "bits" (binary digits), but current machines vary from 12 to 72 or more.

To understand the basis of binary arithmetic, the decimal process of adding 1 to 9 may be considered; there is no higher digit than 9, so that the result of the addition must be written 10. But in binary arithmetic there is no digit higher than 1, so that when 1 is added to 1 a two-digit number must be written, thus:  $1 + 1 = 10$ .

The rules of multiplication and addition shown by tables of conventional decimal arithmetic, which have nearly 200 items, are reduced in binary arithmetic to a few simple rules. Two examples should make this clear. The rule for binary addition is:

$$\begin{aligned} 0 + 0 &= 0 \\ 0 + 1 &= 1 \\ 1 + 0 &= 1 \\ 1 + 1 &= 10 \end{aligned}$$

In other words, two different digits added together produce 1, and two similar digits added together produce 0, but if they are both 1s the machine must carry 1. The corresponding rule for binary multiplication is:

$$\begin{aligned} 0 \times 0 &= 0 \\ 0 \times 1 &= 0 \\ 1 \times 0 &= 0 \\ 1 \times 1 &= 1 \end{aligned}$$

Thus, if either digit is 0, the result is 0, but if neither digit is 0, the result is 1. These rules are very easy to implement in a computer. (See BINARY NUMBERS.)

**Switching Devices.**—Early digital computers used electrical relays as their two-state devices; such machines, some of them quite large, were made in the United States during the early 1940s for military needs. Although they appear grotesque by modern standards, they served a useful purpose in establishing the fundamentals of this technique of computing. These relay machines suffered from unreliability, because of the known uncertainties of the relay contacts, and from low speed (only a few tens of operations per second). Much of the subsequent development of digital machines was devoted to attacking the twin problems of speed and reliability; present speeds of many millions of operations per second are attained, so that the need for reliability is still more imperative. A fault rate of 1 in 1,000,000,000 would in most contexts be regarded as superlatively accurate, but in a computer performing 1,000,000 operations per second it would result in a risk of a mistake every 17 minutes, which most users would find completely unacceptable. Modern computers run many days without a mistake.

The relays, with their slow speeds, moving parts, and vulnerable contacts, were followed in the early 1950s by vacuum tubes, usually in pairs connected so that the current in one turned off the current in the other until the pair was pulsed into the other state. Early computers of this type, using tubes based on those in commercial radio receivers, were unreliable, but improvements in tubes and circuits soon made possible reliable computers with speeds up to 100,000 operations per second. Several thousand tube machines were constructed and put to use, in essence starting the computer age. The main limitations of tube machines are that they are large (up to 30,000 tubes) and costly to operate (as much as 20 to 50 kw. of electrical power for circuit operation and cooling).

In the late 1950s, transistor development had reached a stage where types suitable for computer use became available. Transistors have permitted construction of much smaller and less costly computers that have higher operating speeds (up to 50,000,000 operations per second), much greater reliability, and much less operating expense (a reduction of 30 to 1 in one comparison of tube and transistor machines with similar capabilities). With all newer designs using transistors, the existing tube machines will gradually disappear.

**Storage Devices.**—For use in a binary machine, a device to store one bit must be able to be placed in one of two stable states, corresponding to 1 and 0; must be able to maintain this state indefinitely until changed; must be able to be read or changed at very high speed (up to 1,000,000 times a second); and, because millions of bits may have to be stored, must be very inexpensive. Actually, since not all of these requirements can be met at present by a single type of device, most computers have several types of memories, as discussed below. Although many devices and techniques have been tried, the most successful ones have been based on the principle of magnetic recording. The differences between the different types of storage devices in present use reside in the type and disposition of the magnetic material.

Memories that can be addressed at random at high speed are essential for high speed of computer operation and are found in almost all machines of current design. They are commonly built up of small cores shaped like doughnuts, usually  $\frac{1}{16}$  in. in diameter, which are made of a hard magnetic material and which can be magnetized in either of two directions by currents in wires passing through the hole. Such a core is "read" to discover which state it was in by trying to magnetize it in a fixed direction, usually that corresponding to the state chosen to represent "0." If the core was in the "1" state prior to the read operations, the resulting magnetic flux reversal will cause an electrical pulse to be generated on a sense wire that threads the hole. However, if the core was already in the "0" state, no flux reversal will occur and no pulse will appear on the sense wire. Since the above readout method sets all cores to the "0" state, the stored information is destroyed and must be rewritten after reading if it is to be remembered. This technique, called "destructive read," is used most often because it is the least expensive. For certain applications, particularly military or industrial control operations, where

loss of stored information could be disastrous, nondestructive memory-reading techniques have been developed.

The size of core memories progressed from a maximum of 4,096 ( $2^{12}$ ) words of 36 bits each (a total of 147,456 cores) in the early 1950s to as much as 131,072 words of 48 bits each (a total of 6,291,456 cores) by the mid-1960s. At the same time, speed increased from 100,000 read-write cycles per second to more than 1,000,000, and the cost per bit of storage capacity decreased from more than \$1 to about 20 cents. New techniques involving thin evaporated magnetic films have demonstrated speeds of 10,000,000 read-write cycles per second and offer hope of eventually reducing costs to 1 or 2 cents per bit. Because present costs of film memories are higher than those of core memories, they are now used only as small "scratch-pad" memories to speed up computer operations.

Despite the progress in the random-access memories cited above, they will probably never be large enough (and inexpensive enough) to hold the tens of millions of words needed in many problems. Data infrequently referred to can be stored in slower, less expensive types of memory and transferred to the high-speed memory only when needed. Slow-access stores are typified by magnetic tapes; they use a wide (one-inch) tape similar in many ways to tape used on commercial magnetic-tape recorders. The digits to be stored are recorded as dots of magnetism. There are commonly up to 16 separate tracks, laid parallel across the tape. Although there are often as many as 1,000 bits per linear inch, the number of bits to be recorded and read is so high that tape speeds of 200 in. per sec. are common. To read any particular entry on the tape it is necessary to be able to start and stop the tape in a few thousandths of a second, and the mechanical design of the tape-handling equipment is thus a major problem. The capacity of such a store is virtually unlimited (up to 10,000,000 words per tape reel), and tapes of data or programs may be removed when not in use, freeing the tape mechanisms for other work. The main problem with tapes is the access time, since it may be necessary to traverse the whole tape (requiring a minute or more) to find a desired stored item. Tape stores are generally used only for information that can be processed as it arises or for information that has been prestored in logical order, so that the tape-handling unit does not spend most of its time searching for the required item.

Intermediate between these two types of storage are the magnetic drum and the magnetic disc. A drum can be considered as a wide magnetic tape, carrying from 1 to 200 tracks, wrapped around a drum rotating at about 3,000 rpm. Each digit recorded comes around to the reading point every fiftieth of a second (which is the maximum access time), but the capacity of the store is limited to several tens of thousands of words, except on a few very large and expensive units. The magnetic disc has proved to be a less expensive way of providing the very large, medium-speed stores needed in many applications (e.g., airline seat reservations). A magnetic-disc store in a way resembles the familiar "juke-box" automatic record changer. Up to 20 discs, coated on both sides with magnetic material, are rotated on a common shaft, and a servocontrolled reading head is positioned to read a desired track. Because of this positioning, access time is somewhat longer than that of the drum, but capacities of up to 10,000,000 words per unit are available. Removable discs are also available.

Even larger capacities than those economically provided by discs are desired in some applications (e.g., storing multilanguage dictionaries for language translation), and new types of stores based on photographically recorded spots read with light beams are now appearing. These "read-only" stores (the computer cannot change the recorded data) have access times similar to magnetic discs, and capacities up to 10,000,000,000 words.

**Programming.**—The operations carried out by a digital computer are generally very simple, so that a problem of any complexity must be broken down into a program, which consists of a series of instructions usually expressed in a code similar to that used for numbers and other data. Breaking down a logical problem into component parts, each of which is within the scope of a particular computer, is a skilled vocation, and much of the suc-

cess of early digital machines depended on the ability of individual programmers, since few scientists or businessmen were able to prepare their own programs. Later, with more versatile machines, it became possible and indeed common to devote a part of the machine's capacity to preparing its own detailed program from general instructions fed into it. Automatic coding techniques that relieve the programmer of most of the drudgery allow him to concentrate on the logical problems involved and express his resulting instructions in (almost) plain language. Great progress is being made in the development of computer "languages" for scientific, engineering, and business use that approach natural language and will permit individuals to easily prepare their own programs.

**Scientific v. Business Machines.**—The amount and nature of storage provided depends on the purpose for which the machine is intended; this constitutes one of the main differences between scientific and business machines. In scientific machines the units that carry out arithmetical and logical operations are most important, while the storage capacity is not particularly large. In business machines the provision for arithmetic and logic need not be so generous, but the storage, at all levels, must be copious. The entire documentation of an office, such as ledgers and similar records, the lists of customers' names and addresses with the trade conditions appropriate to each, and the catalogue information referring to the firm's products must be stored. Those data that are applicable repeatedly during a run will be in an integral store such as a core store; other information, applicable to individual customers only, will be on magnetic tapes or discs.

Business machines are also differentiated by the bulk of data fed into and out of them. Computers have been much used to extend the scope of punched-card systems and similar office machinery, and they accept information from card readers capable of reading up to 500 cards (each carrying up to 960 binary digits) per minute. In banking, customer account numbers are commonly recorded on checks with a magnetic ink that can be read directly by the computer. Also used are optical scanners that can read standard printed matter at a rate of a fraction of a second per page by coding each letter and number for the computer. The output of the computer may actuate punches to produce cards for further mechanical handling, or it may produce a typescript output. A high-speed printer suitable for handling the output of a computer will type about 1200 lines of script per minute, all the characters (up to 100 or more) in each line being typed simultaneously. Bills, checks, and address labels can thus be automatically prepared at extremely high speed.

For scientific machines, cathode-ray tube displays (similar to television screens) and graphical plotters are now used to automatically draw plots and graphs, showing the results of calculations, that formerly had to be prepared by hand from numerical data printed out by the computer. In the future, this technique will also be widely applied in industry to automate the process of preparing engineering drawings, particularly as more and more of the work-load of design and engineering is handled by computers.

**Future Trends.**—The advent of new technologies, particularly microelectronics (see INTEGRATED CIRCUIT), promises a continuation of the rapid advancement that has occurred in the computer art. For military and space use, digital computers the size of shoe boxes were constructed in the 1960s that had capabilities comparable to those of computers that filled an entire room only a decade earlier.

Thomas, *Computers: Their History, Present Applications, and Future* (1965). (A. H. Co.; Jo. E. W.)

**COMSTOCK, ANNA BOTSFORD** (1854–1930). U.S. naturalist and artist, a wood engraver of nature subjects, and an influential advocate of nature study in education, was born on Sept. 1, 1854, at Otto, N.Y. She was a graduate of Chamberlain institute, Randolph, N.Y., and Cornell university, Ithaca, N.Y., and studied art at Cooper union, New York city. In 1913 she was made as-

sistant professor and in 1920 professor of nature study at Cornell university. Among her published works are *Ways of the Sun-Footed* (1903), *How to Know the Butterflies*, with J. H. Comstock (1904), *Handbook of Nature Study* (1st ed., 1911), *The Pet Book* (1914), *Bird, Animal, Tree, and Plant Notebooks* (1914) and *Trees of Leisure* (1916). Mrs. Comstock died on Aug. 24, 1930, in Ithaca. (H. Es.)

**COMSTOCK, ANTHONY** (1844–1915), professional U.S. reformer, was born in New Canaan, Conn., on March 7, 1844. For more than 40 years he was the most eminent U.S. crusader against obscene literature and his name came to be loosely used as a synonym for moralistic censorship. He was also active in the suppression of fraudulent banking schemes, mail swindlers, lotteries and medical charlatans. In general Comstock did not concern himself with serious literature but directed his energies against commercial pornography. Occasionally, however, he took action against established writers and the classics on the principle of "morals, not art or literature." He received a public-school education, served in the Union army during the American Civil War and became in 1872 an active worker with the Young Men's Christian association in New York city. He lobbied successfully in 1873 for passage of more stringent laws (called "Comstock laws") against the transportation of obscene matter in the mails. He was also an organizer and chief special agent of the New York Society for the Suppression of Vice. He died in New York city on Sept. 21, 1915. Among his published works were *Frauds Exposed* (1880), *Traps for the Young* (1883) and *Morals Versus Art* (1888).

See Heywood Brown and Margaret Leech, *Anthony Comstock, Roundsman of the Lord* (1927). (H. Ca.)

**COMSTOCK, JOHN HENRY** (1849–1931), U.S. entomologist and author of popular handbooks on that subject, was born in Janesville, Wis., on Feb. 24, 1849. After his graduation from Cornell university, Ithaca, N.Y., in 1874, he pursued further study at Yale university in 1874–75 and at the University of Leipzig in 1888–89. He was instructor and assistant professor of entomology in 1875–78 at Cornell, and, after serving as U.S. entomologist at Washington in 1879–81, was made professor of entomology at Cornell and continued in that chair until 1914 when he became professor emeritus. By his influential work as a teacher and by his researches and writings, he contributed notably to the advancement of entomological science and rose to foremost rank among American entomologists. Besides numerous articles in scientific journals his published writings include: *A Manual on the Study of Insects*, with Anna Botsford Comstock (1895, 1904, 1907); *Insect Life* (1897, 1891); *Introduction to Entomology* (1888, 1920, 1924); *How to Know the Butterflies*, with Anna B. Comstock (1904); *The Spider Book* (1912); and *The Wings of Insects* (1918).

**COMTAT-VENAISSIN**, a former enclave of territory in southeastern France, corresponding to the southwesternmost quarter of the modern département of Vaucluse (q.v.). Bounded on the west by the Rhône, which separated it from Languedoc, it was half encircled from the east by Dauphiné and Provence, the lower course of the Durance river forming its southern frontier. It took its name from the countship of Venaque, southeast of Carpentras. Carpentras, however, was the chief town.

In ancient times the country was inhabited by the Gallic tribe of the Cavarii. Later the countship was part of the kingdom of Burgundy or Provence (see BURGUNDY; ARLES, KINGDOM OF) and passed with it under the distant suzerainty of the Holy Roman emperors, from whom the counts of Toulouse held it as a fief.

Raymond VII of Toulouse ceded it in 1229 to Pope Gregory IX, who left its administration to the French king's representatives. In 1273 Philip III of France decided to give it up to Pope Gregory X. From 1274 it was under a legate till 1791, when it was annexed to France. Avignon (q.v.) was not added to the papal territory till 1348.

See J. Fornery, *Histoire du Comtat-Venaissin et de la ville d'Avignon* 3 vol. (1909–12).

**COMTE, AUGUSTE** (ISIDORE AUGUSTE MARIE FRANÇOIS XAVIER COMTE) (1798–1857), French positivist philosopher, gave

the basic social science of sociology its name and established the new subject in a systematic fashion. He was born at Montpellier on Jan. 19, 1798. His father was a tax official. In 1814, Comte entered the École Polytechnique at Paris, but the institution was temporarily closed in 1816. Comte remained in Paris as a teacher of mathematics, and in 1818 made the acquaintance of Count Henri de Saint-Simon, who contributed many of the concepts that Comte later embodied in his writings. In 1826, Comte started a course of lectures in Paris to expound his ideas as they were developed at this time, but he suffered a serious nervous breakdown and was compelled to abandon them.

From 1832 to 1842 Comte was a tutor and then an examiner at the revived École Polytechnique. In the latter year he quarreled with the directors of the institution and lost his post along with much of his income. During the remainder of his life he was supported in part by such English admirers as John Stuart Mill and by French followers, especially the philologist and lexicographer Maximilien Littré. Comte married Caroline Massin in 1825, but the marriage was unhappy and they separated in 1842. In 1845 Comte had a profound romantic and emotional experience with Clotilde de Vaux, who died in the following year. He idealized this sentimental episode and it exerted a considerable influence upon his later thought and writings, notably in regard to the role of women in the positivist society he planned to establish. Comte was a rather somber, ungrateful, self-centred and egocentric personality, but he compensated for this by his zeal for the welfare of humanity, his intellectual determination and his strenuous application to his life's work. He devoted himself unflinchingly to the promotion and systematization of his ideas and to their application in the cause of human betterment. He died in Paris on Sept. 5, 1857.

**Main Writings.**—In 1822, Comte published his first work, *A Plan for the Scientific Works Necessary to Reorganize Society*, which roughly forecast his intellectual career. It described the intellectual trends of the time and suggested the needed reforms in ideology and social planning. In 1826 he brought out *Considerations on the Spiritual Power*, which was inspired in large part by Saint-Simon and by leading Catholic writers such as Joseph de Maistre and L. G. de Bonald. It foreshadowed some phases of his later religion of humanity. Shortly after this he began work on his first major treatise, *Course of Positive Philosophy*, the first volume of which appeared in 1830 and the sixth and final volume in 1842. He then turned immediately to an even more ambitious project, *System of Positive Polity*; the first volume was published in 1851 and the fourth and final one in 1854. This work both developed his sociological theories and set forth his plan for an ideal society.

Comte published a number of lesser works: *Discourse on the Positive Spirit* (1844); *Positivist Calendar* (1849); *Positivist Library* (1852); *Positivist Catechism* (1852); *Appeal to Conservatives* (1855); *Subjective Synthesis* (1856); and *System of Positive Logic* (1856). Comte's material was well organized and its exposition proceeded in impressively orderly fashion for the most part, but his style was heavy, laboured and rather monotonous. His chief works are notable mainly because of the scope, magnitude and importance of his project and the conscientious persistence with which he developed and expressed his ideas.

**Sources of Comte's Ideas.**—Comte drew many of his basic ideas from earlier writers, going back as far as Plato and Aristotle, but he took them mainly from thinkers of the 18th and early 19th centuries. From David Hume, Immanuel Kant and F. J. Gall he derived his conception of positivism in method and his notions about psychology. Catholic writers like Bonald and De Maistre impressed him with their views concerning a religious framework for social organization. The repudiation of Christianity and the installation of the worship of the Goddess of Reason in the French Revolution stimulated his idea that the religious order should be of a secular nature. From Hume, Kant and Turgot, Comte took over the idea of historical determinism, which was somewhat paradoxically tempered by the notion of a providential order of human development which he adopted from Bossuet, Vico, Bonald and De Maistre. Through Turgot, Condorcet, Burdin and Saint-Simon he conceived his idea of progress and the law of

the three stages (theological, metaphysical and scientific) in the intellectual development of mankind. From the abbé de Saint-Pierre, Montesquieu and Saint-Simon he appropriated the conception of the need for a basic and unifying social science which would both explain the existing social organization and guide social planning for a better future. This social science he called "sociology" for the first time.

Although he later quarreled with him, Comte was most indebted to Saint-Simon who had emphasized the three stages of intellectual development, the need for a new and secularized spiritual order to replace supernaturalism, the belief that social phenomena can be reduced to laws, the conviction that the purpose of the new and fundamental social science should be ameliorative, and that the outcome of all this ideological novelty and systematization should be the guidance of sound social planning.

Comte synthesized these previous ideas with differing emphasis in his various works and in different periods of his career, and added not a few important conceptions of his own in rounding out his system of social philosophy, social planning and sociology. But his main personal contribution consisted in his resolute adoption of the positive or scientific method, from which he strayed at times, and in his impressive achievements in synthesis and systematization.

If Comte relied widely on writers from the past, he paid little attention to what was being produced while he was composing his own works. Once he had worked out his system of thought and social science and had assembled the data and ideas which he regarded as essential for his task, he read virtually nothing more. To an even greater extent than Herbert Spencer, he depended upon his learned friends for such information as he received as to the intellectual achievements of his age but, unlike Spencer, he made very little use of the information he casually obtained in this manner.

**The Positivist Philosophy.**—The main contributions of Comte's positive philosophy fall into five parts: the rigorous adoption of the positive or scientific method; the law of the three states or stages of intellectual development; the classification of the sciences; the conception of the special and incomplete philosophy of each of the sciences anterior to sociology; and the synthesis of the positivist social philosophy which completes, clarifies and unites all the lesser and subordinate philosophies.

Developing further the ideas of Turgot, Burdin and Saint-Simon, Comte held that the evolution of human thought and knowledge passes through the three main stages: the theological, the metaphysical and the scientific, and divided each of these into several substages; but these need not be of concern here. A major imperative of the positivist program is to place the study of society in the third or scientific stage. This Comte attempted to do on a grand scale. But he realized that it would be a slow process, for the theological and metaphysical vestiges inevitably linger on longest in the realm of social science.

Comte's classification of the sciences was based upon the hypothesis that the sciences must inevitably develop in the order of decreasing generality and increasing complexity. Hence, they appeared in the following genetic series: mathematics, astronomy, physics, chemistry, biology and sociology. Each of these sciences draws from and depends upon those which precede it in the series. Sociology not only completes the series but also reduces social facts to laws and synthesizes the whole of human knowledge, thus rendering it equipped to guide the reconstruction of society.

Comte devoted much of the first three volumes of the *Positive Philosophy* to an exposition of the special philosophy of each of the five sciences which precede sociology. But this has been regarded as one of his least successful intellectual achievements, lacking in originality and precision and excessively dogmatic. It did not compare with his broader treatment of the positivist philosophy in general or his elucidation of the province and principles of sociology.

In addition to his system of positivism as such, Comte made important contributions to philosophy in general. His philosophical writings were probably the most powerful inspiration to the development of a scientific orientation in philosophical thought in con-

temporary times. The evolutionism of Herbert Spencer gave this trend a more dynamic pattern. Comte's thinking also had some influence upon the assumptions of the 20th-century philosophical position known as logical positivism (*q.v.*).

**Social Planning and Utopia.**—In his plan for social reorganization Comte proved his own thesis that theological concepts survive longest in sociology. John Stuart Mill and Comte's rationalistic admirers were astonished and shocked when Comte's conception of the ideal positivist society was revealed in his *System of Positive Polity* as a religious utopia. But he had foreshadowed this in his earlier writings. His relations with Saint-Simon had given him a spiritual frame of reference with respect to social reconstruction. His 1826 volume, *Considerations on the Spiritual Power*, indicated that he believed that the organization of the Catholic Church, divorced from its supernaturalism, might well provide an ideal structural and symbolic model for the new positivist society. His episode with Clotilde de Vaux stimulated his mysticism and developed a cult of sentimental womanhood. It had been a cardinal tenet of Comte that any desirable and permanent social improvement must be preceded by an appropriate moral transformation. For the Catholic God, Comte substituted the worship of the Great Being, namely, humanity past, present and future. He called his new faith "the religion of humanity." It was more truly a system of social ethics. The spiritual power of the priesthood was to be independent of and superior to the temporal authority. Comte even worked out a positivist catechism, hierarchy of the sacraments, calendar of the saints, and the like (see *Main Writings* above), but beneath or within this fantastic symbolism there was much realism and substance.

Comte himself was the supreme social planner of the new social system based on the worship of the Great Being. But, he said, his original planning would require detailed guidance and interpretation, constant exhortation, and continuity. To assure these would be the responsibility of the spiritual power lodged in the priesthood with headquarters in Paris. But the priesthood was actually to be made up of secular sociologists, who would work out the details of the new social order, preach the positivist gospel, give advice and counsel, control education and public morality, and arbitrate disputes, although devoid of any material power to enforce their decisions and recommendations.

The actual administration of the temporal power Comte would hand over to the economic leaders, especially the captains of industry—businessmen and bankers. It would be their task to establish and maintain social control and to assure political, social and economic justice, thus making certain that public morality would be upheld. The maintenance of private morality was the province and responsibility of womanhood, which was to be given dignity, discipline and austerity through the monogamous family, indissoluble marriage and perpetual widowhood. But women were to be excluded entirely from public or political life although given special educational advantages. Universal education stressing positivist principles was to be introduced as a cornerstone of the new social order.

**Comte's Contributions to Sociology.**—Comte's extensive contributions to sociology can only be briefly summarized here. He gave this basic social science its name, even though he did not originate the concept or the province of the subject which had already been clearly discerned by his immediate predecessors. But he did greatly extend and elaborate the field of sociology and systematized its content. He anticipated the organismic school of sociologists by regarding society as a "collective organism." Here he anticipated Herbert Spencer by holding that social progress is characterized by an increasing specialization of functions and a more perfect adaptation of organs (institutions). He thoroughly established the theory of social causation by showing how individual acts and motives are determined or conditioned by their institutional setting.

Comte divided sociology into two main fields or branches; social statics, or the study of social organization; and social dynamics, or the general theory of social progress. He held that the underlying principles of social organization are the distribution of functions and the combination of efforts. The former is achieved

through the social division of labour, and the latter by means of the state and government. In its most general sense, social progress is manifested or exhibited through three inevitable stages of social evolution, comparable to those of intellectual development. These are the military-theological, the critical-metaphysical, and the industrial-scientific, thus emphasizing the interrelation of intellectual trends and social change. Material progress also takes place through three stages in which the main activities and interests are, in sequence, conquest, defense and industry. In the realm of moral progress man's social nature had found satisfaction first in the family, then in the state, and finally in the race.

#### Comte's Influence on Later Thought and Policies

Comte's chief service to philosophy consisted in his comprehensive effort to establish the priority of the positive or scientific method, his law of the three stages of intellectual evolution, his classification of the sciences, and his encouragement of a scientific perspective in thought and literature as represented by H. A. Taine, Ernest Renan and Marcelin Berthelot in France, John Stuart Mill in England, and Theodor Gomperz in Germany.

In sociology, his main contribution was to christen the new science and to be its first systematizer. He divided the subject into its two traditional fields of social statics and social dynamics. Next to these should be placed his emphasis on the dominant role of sociology in social planning, a point of view later accepted and promulgated by Lester F. Ward, Ludwig Stein, Leonard T. Hobhouse, Charles A. Ellwood and others. In a special field of sociology, criminology, he promoted the trend toward a secular and social interpretation of crime and its treatment which repudiated the existing savagery.

In the realm of history, Comte left his mark through his law of the three stages of intellectual development which inspired Karl Lamprecht and other students of intellectual history. He laid the basis for social history through his emphasis on the social conditioning of human actions and motives. He greatly stimulated the search for possible laws and stages of historical development. In the area of economics, while he refused to recognize either economics or political science as a separate science, Comte encouraged what came to be known as institutional economics in the hands of Simonde de Sismondi, J. A. Hobson, Werner Sombart, Max Weber and Thorstein Veblen and his disciples. In political science, Comte anticipated the sociological interpretation of politics which was later cultivated by Hobhouse, Robert Michels, Graham Waller, and the students of group activities and interests within the state, notably Ludwig Gumplowicz, Gustav Ratzenhofer, Albion Small and A. F. Bentley.

Comte had a considerable influence on social reform movements especially in England through the work of John Stuart Mill who was more deeply influenced by Comte than by any other French thinker. His religion of humanity not only encouraged reform tendencies in liberal Christian circles but stimulated the rise of secular religious movements such as humanism. Comte has been esteemed in antidemocratic circles from his time to our own as a result of his opinion that the ideal government is one of the intellectually elite, thus foreshadowing Gaetano Mosca and Vilfredo Pareto. He anticipated the managerial system involving the assumption of power by administrators (bureaucrats) in business and government, elucidated a century later by James Burnham and now in operation in different degrees throughout the world (see BUREAUCRACY). His insistence upon universal education aided the educational reformers.

See POSITIVISM; SOCIOLOGY; see also references under "Comte Auguste" in the Index volume.

Certain aspects of the Comtist philosophy are dealt with in *L'Année sociologique* (Paris); in the *Sociological Review* (London); and in the *American Journal of Sociology* (Chicago). (H. E. BAR.)

**COMYN, JOHN**, the name of four Scottish barons of Norman descent who figured prominently in the troubled history of Scotland during the late 13th and early 14th centuries. JOHN COMYN (d. 1274) was justiciar of Galloway and nephew of Alexander Comyn (d. 1290), earl of Buchan, and of Walter Comyn (d. 1258), earl of Menteith, in whose days the family dominated Scotland. The justiciar's son JOHN (d. c. 1300), called "the Black Comyn," was one of the six guardians of Scotland after the death of Alexander III (1286). When Alexander's granddaughter Margaret the Maid of Norway died in 1290, John was one of the 13 claimants to the throne, but he supported his brother-in-law John de Balliol, whom the English king Edward I confirmed as king of Scotland (1292). He joined Balliol's rising against Edward (1295) but was soon forced to submit.

JOHN (d. 1306), called "the Red Comyn," was the only son of the Black Comyn. He also supported the rebellion (1295) of his uncle, John de Balliol, and he raided England in 1296 and was held by Edward as a hostage (1296-97). On his release he became guardian of Scotland and headed resistance to the English after their defeat of Sir William Wallace at the battle of Falkirk (1298). Despite Comyn's victory at Roslin (1303), Scotland was overrun and he submitted to Edward in 1304. Subsequent rivalry with Robert the Bruce (afterward Robert I) ended with Comyn's murder at Dumfries on Feb. 10, 1306.

JOHN COMYN (d. 1308), earl of Buchan and hereditary constable of Scotland, was cousin to his namesake the justiciar and son of Alexander Comyn. He took part in the negotiations which led to Balliol's establishment as king, and with him surrendered to Edward after the rising of 1295. Having helped to crush Wallace, he again changed sides and did not finally submit to the English until 1304. The murder of his kinsman the Red Comyn confirmed his support of the English and enmity to Bruce. (R. G. NR.)

**CONAKRY**, capital and principal port of the Republic of Guinea, Africa, is situated on the small island of Tombo, which is linked to the Kaloum peninsula by a causeway 328 yd. long, and extended by the Los Islands (q.v.). Pop. (1961 est.) 56,000. The town's development dates from World War II. It is a handsome place of wide, parallel avenues with large buildings and bordered with mango trees, and is surrounded by a coastal promenade lined with villas. There are several distinct quarters: the Centre, with

the chief stores; the administrative quarter; Boulbinet quarter to the south, with its picturesque fishing harbour and old streets; Hospital quarter; and Corinthie quarter, a slum of huts with corrugated iron roofs. A suburb has grown up outside the island, residential on the peninsula and industrial along the road to the airport (9½ mi. distant). Conakry is the seat of the Guinea government and the commercial, industrial and intellectual centre of the country. It is the railhead of the Conakry-Niger line, and has an excellent modern port with quays, warehouses and oil storage tanks. The port's progress is the result of the development of agriculture and of the mining industry (iron at Kaloum and bauxite on the Los). (J. D.)

**CONANT, JAMES BRYANT** (1893— ), U.S. educator and scientist, president of Harvard university and U.S. high commissioner for western Germany following World War II, was born in Dorchester, Mass., March 26, 1893. He received his A.B. and Ph.D. (1916) degrees from Harvard university and, after spending a year in the research division of the chemical warfare service during World War I, returned to Harvard as instructor in chemistry. He was advanced in rank to professor of organic chemistry, winning recognition as a brilliant organic chemist. He specialized in research into free radicals, the chemical structure of chlorophyll and the quantitative study of organic reactions. On May 8, 1933, he was elected president of Harvard, succeeding A. Lawrence Lowell; as president he led the university toward a broadening of the social and geographical make-up of the student bodies of the undergraduate college and the professional schools. An early advocate of aid to the Allies in the late 1930s, Conant became a central figure in organizing United States science for World War II, including the development of the atomic bomb. After the war he served as a senior adviser to the National Science foundation and to the Atomic Energy commission. In 1953 he was appointed United States high commissioner for western Germany and in 1955 ambassador. He became known as a defender of the democratic spirit in the new Germany. Returning to the United States in 1957, he took up an earlier interest in public education and conducted studies of the comprehensive high school and the junior high school, on which he reported to both the general public and his fellow educators.

Conant's publications include two textbooks, *Practical Chemistry*, written with N. H. Black (1920), and *Chemistry of Organic Compounds* (1933). He was particularly successful in writing about science for the nonscientifically trained person, as in *On Understanding Science* (1947).

Among his books on educational policy may be mentioned *Education and Liberty* (1953), *The American High School Today* (1959) and *Suburbs and Slums* (1961). (F. KL.)

**CONCA, SEBASTIANO** (c. 1680-1764), Italian baroque painter, created great, animated compositions, superficial but dazzling in colour and brilliant in execution. He was born at Gaeta, and studied at Naples under Francesco Solimena. In 1706, along with his brother Giovanni, who acted as his assistant, he settled at Rome, where for several years he worked in chalk only, to improve his drawing.

He was patronized by Pietro Cardinal Ottoboni, who introduced him to Pope Clement XI; and a "Jeremiah" painted in the church of St. John Lateran was rewarded by the pope with a knighthood and by the cardinal with a diamond cross. "Pool of Siloam" is considered his finest picture.

**CONCENTRATION CAMPS** are internment centres, established outside the ordinary detention system, in which persons are confined for reasons of military or political security, and for punishment or exploitation. Imprisonment usually is by executive decree or military order and frequently includes groups or classes of persons without regard to individual culpability. Concentration camps are thus to be distinguished from prisons in which persons convicted of crimes under civil law are confined, and from prisoner-of-war camps in which captured military personnel are held under the laws of war. They are to be distinguished, as well, from many other camps or centres in which large numbers of persons may be temporarily confined, such as refugee camps, detention stations and relocation centres.

**Military Concentration Camps.**—In periods of hostility, civilian populations sometimes have been concentrated in camps to prevent them from engaging in guerrilla warfare or providing aid to enemy forces, or simply as a means of terrorizing the populace into submission. Upon the failure of Arsenio Martínez de Campos to put down the Cuban rebellion of 1895, the Spanish government sent Valeriano Weyler y Nicolau to Cuba to command the Spanish troops. As a part of his efforts to pacify the country Weyler instituted his "concentration" policy by a decree of Oct. 21, 1896. Under the decree Cuban men, women and children living in rural areas were forced from their homes and "concentrated" in large camps enclosed by barbed wire and guarded by Spanish soldiers. The prisoners were held in deplorable conditions, with little food and inadequate shelter. Protests in the United States and Spain over this inhumane waging of war against civilians led to Weyler's recall. His successor, Gen. Ramón Blanco y Erenas, found that *reconcentrados* were dying by the thousands, and he ordered the concentration camps abolished.

During the 1901-02 period of the South African War the British, under Horatio Herbert Kitchener, adopted similar measures of repression against the Boers. Having withdrawn his garrisons to major centres, Kitchener established concentration camps for the confinement of noncombatants of the republics of Transvaal and Cape Colony. By July 1901 the camps were filled to overflowing, and at the end of the war they contained about 200,000 persons. Although the concentration policy was criticized in England, the system was not abandoned until the cessation of hostilities in March 1902.

While reprisals against noncombatants for hostile acts against occupying military forces are not expressly prohibited by international law, they must be reasonably related to acts of provocation. The concentration camps established by military authority in Cuba and South Africa were excessive measures for military control and were not supportable in law. Even so, confinement was solely for the period of hostilities, and was not characterized by the deliberate mistreatment inflicted upon the inmates of political concentration camps. (See LAWS OF WAR.)

**Political Concentration Camps.**—Concentration camps for political control have been used chiefly in police states in which punitive power may be exercised outside the ordinary judicial system. To a considerable extent the camps have served as the special prisons of the secret police. Persons suspected of opposition to the totalitarian regime have been summarily arrested by the secret police and placed under long or indefinite terms of confinement in the camps. The principal purpose of the political concentration camp thus has been the maintenance of totalitarian control. A secondary purpose has been the utilization of inmates for forced labour. Prisoners have been required to work for wages in food. Those unable to work usually died from starvation, and those who did not starve frequently died from overwork. While political concentration camps have been established, under various forms, in many totalitarian regimes, they have been used most extensively in the Soviet Union and Nazi Germany. Millions of persons have been confined, punished and exploited in such concentration camps.

**Corrective Labour Camps of the Soviet Union.**—During the first years of the Soviet regime the Cheka (All-Russian Extraordinary Commission for Repression of Counterrevolution and Sabotage) was the primary repressive instrumentality of the state. The Cheka was given the power to exile persons to concentration camps without judicial trial. It was replaced in 1922 by the O.G.P.U. (United General Political Administration). At that time there were 23 concentration camps in various locations in Russia.

Although its powers were not absolute, the O.G.P.U. could arrest and send to concentration camps, without trial, persons accused of political offenses, such as espionage and counterrevolution, as well as those accused of certain criminal offenses, such as looting and illegal border crossing. In 1923 the O.G.P.U. established a concentration camp on Solovetski Island in the White sea in which prisoners were first used extensively for forced labour. Thereafter the Soviet concentration camp system became a gigantic organization for the exploitation of inmates through work.

The O.G.P.U. established many corrective labour camps in northern Russia and Siberia, especially during the first five-year plan, 1928-32, when thousands of rich peasants (*kulaks*) were driven from their farms under the collectivization program. The inmates of the camps in northern Russia were used principally in the lumbering and fishing industries and on large public-works projects, such as the construction of the White sea-Baltic sea canal. The inmates of the Siberian camps were used principally in lumbering and mining. In 1932 the O.G.P.U. set up corrective labour camps for gold mining in the arctic taiga along the Kolyma river in far eastern Siberia.

The O.G.P.U. was replaced by the N.K.V.D. (people's commissariat of internal affairs) in 1934. Thereafter the corrective labour camp system was administered by the N.K.V.D. which had its own para-military force. The Stalinist purges of 1936-38 brought additional thousands of political "unreliables" into the camps. By 1939 a vast system of concentration camps, utilized primarily for forced labour, existed across the northern reaches of European Russia and Siberia. These camps were said to be essentially institutions of slavery. Inmates were housed in rough barracks and were inadequately clothed for the severe arctic climate. The standard rations of bread and soup were scarcely adequate to maintain life. Camp commandants were credited with the amount of work produced against the amount of food consumed. As a consequence the prisoners were driven to, and beyond, the limits of human endurance.

The occupation of eastern Poland in 1939 and the incorporation of the Baltic states into the Soviet Union in 1940 led to incarceration in concentration camps of large numbers of non-Soviet citizens from those areas. Following the outbreak of war with Germany in 1941 the camps received prisoners of war and Soviet nationals accused of collaboration with the enemy. After the war, Russian soldiers who had allowed themselves to be captured were sent to the camps. The powers of the N.K.V.D. were transferred to the M.V.D. (ministry of internal affairs) in 1946. Under the M.V.D. corrective labour camps continued to serve as primary instruments for political control over the peoples of the Soviet Union and of the Soviet satellite states.

**Concentration Camps of Nazi Germany.**—In Nazi Germany the concentration camps (*Konzentrationslager*) were first established for the confinement of opponents of the Nazi party. *Reichsmarschall* Hermann Göring, who was responsible for the institution of the concentration-camp system, stated that the camps had been created for the confinement of thousands of leaders of the Communist and Social Democratic parties. But political opposition soon was enlarged to include individuals who opposed the methods of the Nazis and persecuted minority groups, particularly the Jews. In the anti-Jewish pogrom of 1938, 20,000 Jews were taken into "protective custody" by the Gestapo and sent to the concentration camps. By 1939 six major camps had been established: Dachau, Sachsenhausen, Buchenwald, Mauthausen, Flossenbürg and Ravensbrück.

The outbreak of World War II created a tremendous demand for labour in Germany, and Nazi authorities turned to the concentration-camp population to augment the labour supply. From 1940 to 1942 nine new camps were established: Auschwitz, Neuengamme, Gusen, Natzweiler, Gross Rosen, Lublin, Niederhagen, Stutthof and Arbeitsdorf. Thousands of forced labourers from countries occupied by Germany were placed in concentration camps and auxiliary labour camps. Under the "night and fog decree" (*Nacht und Nebel-Erlass*), a terrorist measure, prominent citizens of occupied territories were spirited away by the Gestapo under cover of "night and fog" and secretly imprisoned in concentration camps. Escaped Soviet officer prisoners of war who were recaptured were sent to Mauthausen where they were executed under the "bullet decree" (*Kugel-Erlass*).

The concentration camps were under the administration of the W.V.H.A. (Economic Administration Main office) of the SS (*Schutzstaffel*). They were guarded by special units of the SS known as the death's-head battalions (*Totenkopfverbände*). While severity of treatment depended upon the categories of prisoners confined, conditions in general were degrading and brutal.

Prisoners were used for medical experiments, in the course of which many were maimed, tortured and killed. Housing was so deplorable, rations were so meagre and work was so excessive that few persons could survive long internment. Crematoriums were established in the camps to dispose of the bodies of the dead. Toward the end of the war, when food and fuel supplies became exhausted, thousands died of starvation and disease. The Allied forces found the quick and the dead lying side by side in the barracks. Camp after camp presented a scene of horror.

The most shocking extension of the concentration-camp system in Nazi Germany was the establishment of extermination centres under cover of the war by order of *Reichsführer* SS Heinrich Himmler. These centres, located principally in Poland, were for the primary purpose of the mass murder of unwanted populations, particularly the Jews. The elimination of such populations was part of the Nazi plan to develop a "master race." Victims were shipped to the camps in freight trains. Those who were not fit for heavy manual labour were sent at once to gas chambers which were usually disguised as bathhouses. Children as well as adult men and women were exterminated in the gas chambers. Bodies of the dead were removed by special details of prisoners and were burned on the ground or in the crematoriums. Everything of value was taken from the victims, including even the gold fillings extracted from the teeth of corpses. The most notorious of the extermination centres was the concentration camp at Auschwitz (Oświęcim), Pol. Rudolf Hoess, the commandant of Auschwitz, confessed to the extermination of 2,500,000 people, but later gave 1,000,000 as the number who died in that camp.

**CONCEPCIÓN**, province of south central Chile lying almost entirely within the coastal mountains, is bounded by the province of Ñuble on the north and east, Bío-Bío and Cautín on the south and the Pacific on the west. It is approximately bisected by latitude 37° S. One of eight provinces created in 1826, Concepción was reduced to 2,193 sq.mi. by the segregation of territory to form Ñuble, Bío-Bío, Malleco, Cautín and Arauco provinces. Concepción is the third province in population (539,450 in 1960) and in population density. The city of Concepción (*q.v.*) is the provincial and departmental capital. Lesser administrative centres are Talcahuano, site of a major naval base, Coronel (*q.v.*), a coal-mining centre, Tomé and Yumbel.

For many years Chile's third industrial centre, Concepción produced in the 1950s 10% of the manufactured goods, 7% of the mineral wealth (value) and about 8% of the timber (volume). Iron and steel, textiles and food products are major manufactures. Coal (about 80% of the national output) and glass and ceramics raw materials are the chief mineral products. Tree farms (pine and eucalyptus) yield most of the timber. Although the climate is temperate and humid, the soils are among the least productive in Chile. Only the vineyard acreage is significant. Nevertheless, a variety of food crops and livestock is raised for the markets of Coronel, Lota (*q.v.*), Concepción, Talcahuano-San Vicente and Penco-Tomé. Double rail communication with the Santiago-Puerto Montt railway is made by way of the Bío-Bío valley or by the Itata and San Rafael valleys.

(J. T.)

**CONCEPCIÓN**, third largest city of Chile, provincial and departmental capital and a major educational and manufacturing centre, is located in latitude 36° 50' S., longitude 73° 06' W. Pop. 168,059 (mun.). The city is an episcopal see, and the seat of an appellate court and of the University of Concepción. The city's commercial and industrial prominence may be related to a number of geographic assets. Concepción bay, to the north, is large and protected; the Bío-Bío river, which enters the sea just below the city, provides a corridor through the coastal mountains to a valley region where agricultural and forest industries are well developed. The river's volume and hydroelectric potential are ample to meet foreseeable regional industrial and domestic requirements. Over

90% of Chile's coal is mined within 55 mi. of the city. The railway serving the major mines ends in Concepción, as do the railways which follow the Bío-Bío and Itata rivers into the interior. The Itata railway links the east-shore Concepción bay industrial and resort towns of Lirquén, Penco and Tomé (textiles, sugar and wine processing, glass and ceramics, coal mining). A local railway serving the southwestern side of the bay joins Talcahuano, Huachipato and San Vicente with Concepción. Talcahuano is a major naval base, a commercial port for the region from Talca to Temuco and, like San Vicente, a source of Santiago's fresh and preserved sea food. Huachipato, a planned industrial town, is the site of a modern steel mill, built in the late 1940s. Concepción's industries include textiles, food processing, woodworking and brewing; across the Bío-Bío is a paper factory and upstream is the Chiguayante cotton mill. The city has an attractive university campus and adjacent residential area. Concepción, founded on the present site of Penco in 1550, was twice burned by the Araucanians (in the 1550s) and struck by several earthquakes, two of them followed by tidal waves (1730, 1751). In 1754 the city was transferred to the present site. Serious earthquakes have continued (1835, 1898, 1922, 1939, 1960).

(J. T.)

**CONCEPCIÓN**, a department of north central Paraguay, lies between the Apa river on the north and Ypané on the south, and is bounded on the west by the Paraguay mainstream. The terrain is swampy lowland in the west, rising eastward into hilly country. Area 6,970 sq.mi. Economic activities centre around lumbering, cattle raising and subsistence agriculture. The principal settlements are Concepción, the capital, Horqueta, Loreto and Belén, all in the southwest of the department. Of the population of 86,336 (1962), 90% live south of the Aquidabán river, in the districts served by these towns. A road links Concepción to Brazilian centres and a narrow-gauge railway serves Horqueta.

(G. J. B.)

**CONCEPCIÓN** (VILLA CONCEPCIÓN), the principal town and river port of northern Paraguay, lies on the Paraguay river near the mouth of the Ypané river. Pop. (1960 est.) 20,642, including many with an admixture of Indian blood. It is an export point for cattle, lumber and yerba maté, and a distributing centre for merchandise brought up the Paraguay river from Argentina and from Asunción, the national capital, which lies 134 mi. to the south. It has a considerable trade with the Brazilian province of Mato Grosso, to the north, as well as with the quebracho ports of Casado and Pinasco. It is also linked by internal air services with the capital. Founded in 1773, it was an important logistic point during the Chaco war, 1932-35, and has remained a garrison city. It is the headquarters of the bishop of the Chaco. A metre-gauge railway eastward to Horqueta serves a cattle-raising and lumbering area.

(G. J. B.)

**CONCEPT AND CONCEPTION.** In philosophy the word "concept" (of which "conception" is an older equivalent) is very frequently employed: it is indeed so convenient as to be almost indispensable, though its use has sometimes been thought to raise difficulties. A typical instance of its use is in the title of Gilbert Ryle's book *The Concept of Mind*, where it implies that the purpose of the author is not to investigate empirically (*e.g.*, by the methods of psychology) the mind itself, but to investigate the salient logical features, or in the author's phrase the "logical geography," of the language in which we speak of the human mind. Similarly, investigations of the logical features of discourse about pleasure or duty or remembering would be said to be concerned with the concepts of pleasure or duty or memory. Derivatively, to use, or to be able to use, the linguistic expressions in question would be said to be to apply, or to possess, those concepts. The convenience of the word "concept" is that it supplies a brief mode of referring to the interest of philosophers in logical, or linguistic, problems, as distinct from the interest of other inquirers in empirical (nonlinguistic) matters of fact. Its use has, however, been occasionally deplored, on the ground that it might suggest that philosophers are concerned with nonsensible entities, "objects of thought" or "mental contents," and thus might actually obscure the essentially linguistic, or logical, character of philosophical problems. It need not be denied that the use

of this expression might, as indeed might the use of any other, prove sometimes misleading; however, the danger of this is an insufficient reason for renouncing altogether the use of so convenient a term. See also **ABSTRACT AND ABSTRACTION; CONCEPTUALISM; UNIVERSAL.**

(G. J. Wk.)

**CONCEPT FORMATION, PSYCHOLOGY OF.** A prominent aspect of the human thought process is the utilization of abstraction, in which generalized categories are used to represent a diversity of particular objects and events. The "general ideas" which are used for classes of items are called concepts (see **CONCEPT AND CONCEPTION**), and the process by which the person comes to give a common response (usually a name) to a general class of objects which despite differing details have certain characteristics in common is called concept formation. The relationship between universals and particulars has been discussed by philosophers since the time of Plato, but not until the 20th century was the problem given experimental study.

Concepts develop slowly through experience. They are usually derived from a series of concrete examples, or instances, some of which are found to be members of the class being derived and others of which are not. The first type of example is commonly referred to as a positive instance (a member of the class) and the latter as a negative instance (not a member of the class). Thus the child is told on many occasions that the animal he sees is a dog, but on other occasions he is told that his teddy bear or the family cat is *not* a dog. Depending on its nature, positive and negative instances have varying utility in conveying a concept. In general, positive instances seem to be more effective in learning, although with complex concepts negative instances are essential to limit appropriately the possible range of generalization.

Observation of and interviews with children in the process of learning concepts at successive ages have had an important influence in the study of how concepts are acquired. Jean Piaget analyzed into four general stages the development of concepts in children. During the first stage the child shows discrimination of objects by a characteristic reaction to particular objects. In the next stage he employs words to stand for particular objects but not for classes of them. In the third stage the child responds symbolically to a class of objects but is unable to give an adequate verbal formulation of the concept. During the fourth stage the child is able to give an acceptable definition of the concept. These stages are not, of course, perfectly clear-cut, and there is considerable overlapping between them.

A pioneer study by C. L. Hull involved the learning of nonsense syllables to various symbols drawn to resemble Chinese characters and devised to have certain common characteristics imbedded in them. Hull found that the appropriate nonsense syllable was learned to each class of stimulus on the basis of the hidden characteristics, although in many cases the learners were not able to verbalize the basis on which they did this. Extensive further study was undertaken by E. Heidbreder, who believes that concepts involving concrete objects are more readily learned than those involving spatial forms or abstract numbers.

Appropriate concept formation is dependent upon the functioning of the nervous system and brain. Studies of the effects of brain damage, particularly among wounded soldiers, indicated that injury to the frontal cortex of the brain impairs the person's ability to utilize abstract concepts but has much less effect on his dealing concretely with particular objects. For example, one of the patients studied by K. Goldstein and M. Scheerer could readily drink out of a glass filled with water but was unable to demonstrate how to drink when the glass was empty. Another patient could use a generic term like flower in a particular way (as, "I grow flowers in my garden") but could not deal with the abstract concept of flower.

Somewhat related phenomena are found in studies of mental patients, particularly those with schizophrenia (*q.v.*). L. S. Vigotsky, a physiologist, who devised an important clinical test used in the study of conceptual capacity, advanced the thesis that thinking in schizophrenics is a regression to childlike thinking. Significant studies of thinking in schizophrenia were carried out by E. Hanfmann and J. Kasanin, who found marked deterioration

in the pattern of concepts utilized by schizophrenics. There was, however, considerable variability, the lowest levels of conceptual functioning occurring consistently only among patients also having organic damage. Since schizophrenic patients typically have severe emotional difficulties, it is not clear to what extent the deteriorated performance is attributable to personality disturbances rather than to changes in intellectual functioning.

Most of the concepts the child learns and the adult uses in his everyday thinking exist ready made in the culture in which he is brought up. The task of the individual is not to form them but to acquire them by means of his relations with others. The invention of entirely new concepts is a much rarer and much more difficult task. This is, of course, particularly characteristic of scientific activity. Here, in addition to the inductive type of concept attainment which has been discussed, there is need for inference of the type classically labeled deduction and also for creativity to develop novel combinations not formerly considered. Concepts involving relationships where there are long time lapses between an event and its consequences, or concepts involving contingencies and interdependence, are particularly difficult to develop. There are also frequently motivational resistances to the acceptance of new concepts which have to supplant those derived from earlier experiences. See also **CHILD PSYCHOLOGY; THINKING AND PROBLEM SOLVING.**

**CONCEPTUALISM** (from "concept"), in philosophy, a term applied by modern writers to a scholastic theory of the nature of universals, to distinguish it from the two extremes of nominalism and realism. The scholastic philosophers took up the old Greek problem as to the nature of true reality, whether the general idea or the particular object is more truly real. Between realism which asserts that the *genus* is more real than the *species*, and that particulars have no reality, and nominalism according to which *genus* and *species* are merely names (*nomina, flatus vocis*), conceptualism takes a mean position. The conceptualist holds that universals have a real existence, but only in the mind as the concepts which unite the individual things; e.g., there is in the mind a general notion or idea of boats, by reference to which the mind can decide whether a given object is, or is not, a boat. On the one hand "boat" is something more than a mere sound with a purely arbitrary conventional significance; on the other it has, apart from particular things to which it applies, no reality; its reality is purely abstract or conceptual. The term was enunciated by Abélard in opposition to Roscelin (nominalist) and Guillaume de Champeaux (realist). Abélard held that it is only by becoming a predicate that the class-notion or general term acquires reality. Thus similarity (*conformitas*) is observed to exist between a number of objects in respect of a particular quality or qualities. This quality becomes real as a mental concept when it is predicated of all the objects possessing it. Hence Abélard's theory is alternatively known as sermonism (*sermo, "predicate"*). His statement of this position oscillates markedly inclining sometimes toward the nominalist, sometimes toward the realist statement, using the arguments of the one against the other. Hence he is described by some as a realist, by others as a nominalist. When he comes to explain that objective similarity in things which is represented by the class concept or general term, he adopts the theological Platonic view that the ideas which are the archetypes of the qualities exist in the mind of God. They are, therefore, *ante rem*, *in re* and *post rem*, or, as Avicenna stated it, *universalia ante multiplicitem, in multiplicite, post multiplicitem* ("universals exist before, in, and after the multiplicity of their particulars"). The whole controversy suffers from a tendency to confuse "idea" in the sense of a concept or notion in the mind with "idea" in the Platonic sense of an ultimate archetype of phenomenal objects. (A. Wo.)

**CONCERT.** The concert is a social institution for the performance of absolute, as distinct from religious or dramatic, music which developed to its present form from the informal music-making of the 17th century. The social influences affecting the concert also affected the music conceived for it, and the evolution in music from Mozart to Beethoven has a counterpart in the aristocratic, as opposed to the democratic, patronage of the concert. Similarly, cosmopolitan aspects of music in the second half of the 20th century are associated with the increasingly international outlook of concert audiences.

Early forms of the concert were associated with university activities. In the first half of the 18th century many German universities maintained a Collegium Musicum for the performance of chamber music, and "music meetings" were regularly held at Oxford and Cambridge. Gatherings of amateurs to hear music had been a feature of the Italian academies of the Renaissance, notably those at Bologna and Milan founded in the 15th century. Like the French academies that succeeded them, they fostered music as one of the humanities and anticipated in this respect the function of 18th-century concert patrons. The more important Italian and French academies were, however, principally concerned with exploring the borderlands of music and poetry, and these opened a way to the opera rather than to the concert.

The first public concerts for which admission was charged were given in London by the violinist John Banister at his home in Whitefriars in 1672. In 1678 Thomas Britton, a charcoal seller, established weekly concerts in a loft in Clerkenwell at the subscription rate of 10s. a year. Handel and Pepusch were among the performers at these humble but historic concerts which were the forerunners of several other London series, particularly in the neighbourhood of Covent Garden.

Concerts of instrumental and vocal music were frequently given at the homes of the nobility in France in the 17th century. The first public concerts in France were the Concerts Spirituels, organized by the composer Anne Danican Philidor on days of religious festivals when the Opéra was closed. These flourished in Paris from 1725 to 1791. Closely associated with the development of the symphony and bringing the 18th-century repertory to a wide public, the Concert Spirituel served as a model for similar concert societies in other countries.

In the second half of the 18th century the symphonies of Haydn and Mozart were introduced in England at the professional concerts, and Haydn wrote a famous set of 12 symphonies for performance in London at the Salomon concerts. Earlier, concerts reflecting the social elegance of 18th-century London were given in elaborate settings at the gardens of Vauxhall, Ranelagh and Marylebone. An English equivalent of a *fête galante* was suggested by the masquerades and Handeliana opera singers at these pleasure gardens where the programs ranged from works by the seven-year-old Mozart to popular songs of the day. Something of the spirit of the London garden concerts was revived at the end of the 19th century at the Crystal Palace concerts in London. Among the numerous 18th-century concert societies in Germany and Austria the Gewandhaus concerts at Leipzig, dating from 1781, and the Tonkünstlersocietät (Musicians' society), founded in 1771 in Vienna, were later to be associated with the great figures of romantic music. The court concerts given by the orchestra of the elector palatine between 1743 and 1778 at Mannheim, described by Charles Burney as "an orchestra of generals," reached the highest standard of orchestral playing in Europe at that time.

A change came at the beginning of the 19th century when concerts attracted audiences drawn from a wider social range. New concert societies were formed to meet the demands of a growing democratic spirit. Many societies, formed when the symphonies of Beethoven and the romantic works of Berlioz were first heard, exist to the present day, notably the Philharmonic society (later, Royal Philharmonic society) in London, the Concerts du Conservatoire in Paris and the Gesellschaft der Musikfreunde in Vienna.

So far concert giving had been mainly confined to England, France, Germany and Italy. With the growth of nationalism concert societies were formed for the promotion of national music in many European countries, notably the Russian Music society

founded in 1859. In the United States concerts had been given in the 18th century at New York, Philadelphia and Boston, and also at Charleston, S.C., where a St. Cecilia society was founded in 1762 and where, five years later, concerts were inaugurated under the title "New Vauxhall," on the model of the London garden concerts. But the main U.S. contribution to concert activity came with the foundation in the 19th century of symphony orchestras in several towns. Prosperity attracted European artists and enabled high standards to be reached by U.S. musicians. From the early 20th century, concert activity in the larger U.S. cities attained at least the level of that in European centres.

In the 20th century, and particularly after World War II, concert activity was greatly stimulated by the radio and the phonograph. Larger concert halls were built and orchestral and chamber-music concerts became one of the main attractions at music festivals. Concert societies were established in countries of the British Commonwealth and South America. Others sprang up in India and Japan. With the world-wide popularization of music concert repertories were, however, marked by a new trend. Well-established works of the classical and romantic periods were generally more favoured than contemporary works. On the other hand, standards of execution at concerts, particularly of instrumental works, were noticeably higher. Orchestras, as well as soloists, traveled freely from one country to another, and concerts even in provincial towns, sometimes the scene of a music festival, reached a standard which must have been unknown in the main centres of concert activity in the 19th century. (E. L.R.)

**CONCERTINA**, a musical instrument of the free-reed class (see WIND INSTRUMENTS), patented by Sir Charles Wheatstone in London, 1829. Hexagonal hand bellows are fastened between

BY COURTESY OF C. WHEATSTONE AND COMPANY  
EARLY CONCERTINA MADE OF ROSEWOOD AND LEATHER WITH IVORY KEYS AND MOTHER-OF-PEARL PALLETS: BY SIR CHARLES WHEATSTONE: c. 1829

two sets of boards that carry the reeds in fraised sockets, and also the pallet valves and finger buttons by which air is selectively admitted to the reeds. The reed tongues, of steel or brass, are attached to their individual brass frames by screwed plates. The concertina employs "double action" (see ACCORDION), each note being given by a pair of reeds, one to sound on the press of the bellows, the other on the draw. In the original and subsequently the most usual model, the chromatic scale is divided between the two hands; in some later models, as the duet-system concertina, a chromatic scale is provided for each hand.

Wheatstone's other invention in this field, patented in 1829, was the Symphonium. This was a chromatic mouth organ with reeds contained in a small nickel-silver box and controlled by finger buttons at the sides. The blowing hole was at the back of the box, and the reeds (one for each note) were all sprung to be sounded on the blow, none on the draw. The patent also describes a bellows attachment for the Symphonium.

After the great days of the concertina virtuoso in the 19th century, from Giulio Regondi to Alexander Prince, the instrument gradually became superseded from c. 1910 by the improved continental accordion. See also HARMONIUM. (A. C. BA.)

**CONCERTO**, in music, a term used since about 1700 as the title for compositions in which the skill of a single virtuoso instrumentalist is set into relief against an orchestral background. The word has two, apparently contradictory, meanings: first, it describes music played in consort, i.e., together; second, it describes music characterized by a conflict between separate groups of instruments with different tonal qualities.

**The Early Concerto.**—The early history of the concerto is not easy to trace because of this confusion in meaning and because of the inexact application of the term—a difficulty that is also encountered with the sonata and the symphony. The word "concerto" first makes its appearance in late 16th-century Italian

sources: in anthologies of music by Andrea and Giovanni Gabrieli (1587), Cristofano Malvezzi and Luca Marenzio (1591) and Adriano Banchieri (1596); and in the title of a treatise on instrumentation by Ercole Bottrigari, *Il desiderio, ovvero de' concerti di varij strumenti musicali* (1594). In these books, as in dozens of others published during the first 40 years of the 17th century, the Italian term "concerto" is exactly synonymous with the Latin *concertus*, the English "consort" or the French "ensemble." A concerto of this time was a comparatively short piece of polyphonic music for a relatively small number of singers and players, or players alone, each performing an individual part of no particular technical difficulty. The ensemble was usually welded together by the accompaniment of an organ, harpsichord or lute, and the performers were expected to improvise their own embellishments to their written parts. Such a style could only arise in cities like Venice, where there was a long tradition for elaborate ensemble music on great church and state occasions, or at the courts of wealthy art-loving despots (e.g., the Medici of Florence); all the early concertos are associated with such surroundings. In many early concertos the players were arrayed in two or more groups so that the music formed an antiphonal dialogue. In others—notably the very influential *Concerti ecclesiastici* of Ludovico Viadana (1602)—the music is what now would be termed a motet or, more rarely, a madrigal for one or more solo voices, accompanied by the organ and sometimes by other instruments as well.

Throughout the first 40 years of the 17th century the concerto remained an Italian form, practised almost exclusively by Italian composers, and it retained its connotations of ceremony, the church and court, and improvised embellishment. Between c. 1640 and 1680 the word disappeared altogether, for reasons that are far from clear, in favour of sonata or sinfonia (for instruments) and cantata (for voices). When it reappeared (Giovanni Bononcini's *Concerti da camera*, 1685; Giuseppe Torelli's *Sinfonia e concerti*, 1692; Giulio Taglietti's *Concerti e sinfonie*, 1696) its meaning had become restricted to instrumental music, and it has remained so ever since. Concertos of this date are distinguishable from the trio-sonata (for two violins, cello and keyboard) only in that the composers appear to have envisaged several players to a part. An attempt also seems to have been made at distinguishing between the church concerto—solemn, pompous, contrapuntal—and the chamber concerto, which was more light hearted and less intricate (see CHAMBER MUSIC).

**The Concerto Grosso.**—By 1700 or so the viola had become an integral part of the ensemble and each violin part had forked into two, one for an accomplished soloist and the other for his less proficient colleagues. This orchestral ensemble of strings and keyboards was usually handled by composers as a double body: a *concertino* ("little concerto") consisting of the old trio-sonata combination of two violins, cello and keyboard; and a *ripieno* ("filling out") of strings in four or five parts, with a second keyboard. Music for such an ensemble was called a *concerto grosso* (a term first encountered in 1698), and the style was perfected by Torelli (1698), Tommaso Albinoni (1700), Arcangelo Corelli (published posthumously in 1714) and Antonio Vivaldi (1710–20). Most of this music was composed in Rome, Bologna or Venice during the years from 1680 to 1720; it was widely disseminated, above all by the enterprising though piratical music publishers Estienne Roger of Amsterdam and his rival John Walsh of London; and it was widely imitated, by Handel and Bach among many others.

Soon the *concerto grosso* broke into two diverging forms: the solo concerto for a single soloist, and the orchestral concerto for an ensemble of strings, woodwind and accompanying keyboard. Vivaldi took the lead in the development of both these forms, and he also established the pattern of an animated rhythmic first movement, an expressively singing slow movement, and a high-spirited brilliant finale. His hundreds of concertos include 71 (printed) violin concertos, 27 cello concertos, 37 bassoon concertos and three oboe concertos, as well as many orchestral concertos for highly diversified ensembles. Bach and Handel were the first to write concertos for a solo keyboard instrument—they were renowned as virtuosi on the harpsichord and organ, just as Vivaldi was on the violin—and they also carried the development of the orchestral

concerto a stage further, notably in Bach's set of six Brandenburg concertos composed between 1716 and 1721. Each of the Brandenburg concertos displays a different combination of soloists, but at least three of them belong to the repertory of chamber music rather than to that of the symphony orchestra since all the parts are for single players.

By 1730 Vivaldi's three-movement form (quick, slow, quick) had become standard throughout Europe. Its dramatic elements of contrast and display appealed instantly to an age that was mad about opera; Bach's *Italian concerto* for unaccompanied two-manual harpsichord is not only a perfect example of the genre but also demonstrates how it could be transferred intact to a single instrument. Such a work as this is very close to the classical sonata, concerto or symphony of the next generation, lacking only the minuet and trio, and the new structure of sonata form. With the concertos of Bach's sons Carl Philipp Emanuel and Johann Christian, the bridge between the two styles is crossed into the familiar territory of Mozart, Haydn and Beethoven. In their music the violin at last yielded its supremacy as a solo instrument and the newly perfected pianoforte took over instead. Mozart composed six concertos for violin, but nine for piano; Haydn nine for violin, 20 for piano; Beethoven one for violin, five for piano.

**The Classical Concerto.**—During the classical period the concerto steadily increased in length, brilliance and emotional content; the listener found it ever easier to identify himself with the soloist's problems and triumphs, as an analogue with his own attempts to make his way in the world, and the concerto soon became the favourite among all forms of concert music. The piano's increasing power permitted an ever richer and louder orchestral accompaniment; its keyboard was extended to higher and lower notes until its range exceeded that of all other orchestral instruments put together; and the piano concerto became more and more an adventure in contest and endurance, rather than an essay in contrast and elegance. Small wonder that the great romantic composers of the 19th century chose it with such unanimity: two piano concertos each by Weber, Mendelssohn, Chopin, Liszt, Brahms; one each by Schumann and Grieg; three by Tchaikovsky. The array of violin concertos by the same composers makes a striking comparison: one each by Mendelssohn, Schumann, Brahms and Tchaikovsky.

Some special developments in the concerto during the classical and romantic periods are worth noting: (1) the appearance of concertos for almost every instrument of the symphony orchestra (e.g., Haydn's for trumpet, and cello; Mozart's for horn, bassoon, clarinet, oboe, flute and harp; Domenico Dragonetti's for double bass; Rimsky-Korsakov's for trombone); (2) the growth of the accompanied cadenza, finally reducing the soloist's improvisatory freedom to nil; (3) the cyclic form adopted by Liszt for his concertos, in which the three movements become welded together into one long fantasia; (4) the single-movement concerto or *Konzertstück*; (5) the introduction of new concerto forms (e.g., César Franck's symphonic variations for piano and orchestra); (6) the return of the multiple concerto (concertos for two or three soloists are usually known as double or triple concertos, e.g., those by Beethoven, Schumann, Brahms, but the term *sinfonia concertante* is preferred for a work in which these players have a less dominating part, e.g., Mozart's beautiful *sinfonia concertante* for violin, viola and orchestra, K. 364); (7) the ever increasing technical difficulty of the solo parts.

**The Concerto in the 20th Century.**—By 1900, as the result of more than a century of development, the concerto had lost all contact with the form perfected by Mozart; 20th-century composers have worked new veins. Some composers have tried to revive the ideals in style or sound of the early 18th-century concerto, occasionally by using single instruments for every part of the texture (Ernest Bloch, Gustav Holst, Vincent d'Indy, Henk Badings, Goffredo Petrassi, Paul Hindemith, Igor Stravinsky, Manuel de Falla, Francis Poulenc). Others have sought to even out the disparity in technique between soloist and accompaniment by writing concertos for virtuoso orchestra (Hindemith, Béla Bartók). A third group has continued to ride the tiger of virtuosity in solo concertos, not for its own sake but as a means of

personal expression (Sergei Rachmaninoff, Edward Elgar, Sergei Prokofiev, Dimitri Shostakovich, Arnold Schönberg, Alban Berg, Michael Tippett, William Walton). A fourth group has endeavoured to cure the elephantiasis afflicting the late 19th-century concerto by writing much shorter works, reviving for this purpose the diminutive term *concertino*, which first appeared on a title page of 1687 and already had been adopted by Weber for his clarinet concertino, opus 26; among them are John Carpenter and Walter Leigh.

Such new developments as these show that the concept of the concerto is far from outworn. Audiences will always enjoy a contest, provided its rules are comprehensible; they will always enjoy a musical debate, provided the language is neither abuse nor gibberish; and they will always enjoy observing a virtuoso in action, for it is the most exciting of all musical experiences.

**CONCESSIONS**, a term embracing grants by a state to citizens, aliens or another state. A concession may signify a grant by one state to another of political rights in its territory; also a grant, franchise, contract, charter or licence by a state to an individual, a corporation or another state to carry on a specified economic enterprise in its territory. Before World War I the economic concession was used to bring economically undeveloped countries into an expanding international economy.

**Origin and History.**—In the middle ages the term "concession" apparently meant a grant, usually of land, from a ruler. After the Europeans' discovery of distant lands, concessions took the form of charters granting lands and some measure of sovereignty to companies, such as the Massachusetts company and the British and Dutch East India companies, and to individuals such as William Penn and Lord Baltimore. The more recent history of concessions has paralleled the expansion of industry. The 19th century saw the establishment both of economic concessions by agreement with the rulers of economically undeveloped regions and of political concessions as a substitute for the outright acquisition of a colony or to provide a transportation link such as a canal or a railroad. Economic and political concessions were not always easily differentiated. Economic concessions sometimes served as indirect means of political control of weak states. The rise of Asian and African nationalism, particularly after World War II, gave a new prominence to the concession as a means of making capital and technical skills available to undeveloped states.

**Political Concessions.**—Political concessions, usually set forth in treaties between governments, often embrace grants of partial or total sovereignty, perhaps over a commercial port or a military, naval or air base. Examples of Chinese concessions include railways and such ports as Macao (to Portugal in 1557), Kiaochow (to Germany in 1898), Port Arthur (to Russia in 1898), Weihai-wei (to Great Britain in 1898) and part of Tientsin (to Belgium in 1902). Similar was Cuba's concession of Guantánamo bay to the United States in 1903. Although a concession generally takes the form of a lease, the extent to which sovereignty could be effectively transferred is seen in the manner in which Port Arthur was shuttled back and forth between Russia and Japan, with China a powerless bystander. See also **IMPERIALISM**.

Also of a political nature were grants of sovereign rights such as that by the sultan of Borneo to Sir James Brooke (q.v.). "Concessions within concessions" occurred in the late 19th century when chartered companies such as the Royal Niger company gained concessions from native chiefs and in turn granted them for development of industries and natural resources.

The Suez canal involved investment both for profit and for political purposes. The canal was constructed and operated in accordance with concession agreements made by Ferdinand de Lesseps and the khedive of Egypt in 1854 and 1856 and confirmed by the sultan of Turkey in 1866. These agreements, together with the declaration of 1873 and the nine-power treaty of 1888, established the principle of unhampered navigation for

merchantmen and warships of all nations in peace and war, subject to regulations concerning tolls, pilotage dues, etc. The concession agreements provided that a Universal Suez Maritime Canal company should be established for a period of 99 years from the opening of the canal, which occurred in 1869. This joint-stock company was financed by Egypt and by private investors, chiefly French. In 1875 for political and commercial reasons Great Britain purchased the khedive's holdings, amounting to nearly 44% of the shares. In 1949 the subvention to Egypt was increased to 7% of gross profits. On July 26, 1956, Pres. Gamal Abdel Nasser of Egypt announced nationalization of the canal. Western opposition and efforts by users of the canal to establish an international operating authority proved futile. In 1958 the shareholders agreed to settle for retention of external assets and liabilities and payment by Nasser's government of £28,300,000, at least 40% in sterling and the remainder in French francs, payment to be completed on Jan. 1, 1964.

Amid considerable political and diplomatic maneuvering, the Panama canal concession, originally acquired by L. N. Bonaparte-Wyse and associates from Colombia in 1878, passed to a French corporation and finally to the United States. By the treaty of Nov. 18, 1903, the United States guaranteed the independence of the new republic of Panama in exchange for a grant in perpetuity of the use of a zone ten miles wide, exclusive control therein for sanitation, police, judicial and other purposes, the right to fortify and defend the canal and the right to intervene when necessary to preserve order in the cities of Colón and Panama. Panama received an immediate payment of \$10,000,000 plus an annuity of \$250,000 beginning after nine years. In 1921 Colombia was accorded \$25,000,000 in compensation for losses suffered.

**The Nature of Economic Concessions.**—Economic concessions fall into two major categories: (1) public utilities; and (2) exploration for and exploitation of natural resources. Among the public utilities embraced have been cables, telegraphs, shipping, lighthouses, roads, sewers, hospitals and air transportation. Natural resources exploited have included petroleum and other hydrocarbons, minerals, rubber, timber and agricultural products. The instrument of concession is usually an agreement or contract in which both the granting state and the concessionaire accept mutual obligations toward each other. Unless economic concession agreements are between states, they are not treaties.

**Mining Concessions.**—Mining has been conducted by concession since the middle ages. Today in much of the world concession is the necessary method for mineral and oil extraction because either constitution or statute vests the subsoil in the state. Elsewhere the concession method can serve the interests of conservation. Where the subsoil is owned by the state the government concedes the privilege of working government property. Otherwise, the privilege of mining depends upon both agreement with the surface owner and contractual permission or licence from the state. International mining concessions provide the conceding state with both income and a basis for industrial development, while the concessionaire's state acquires more certain access to industrial and strategical minerals, including fissionable materials, which distribution governments try to control.

**Oil Concessions.**—Development of the internal-combustion engine rendered petroleum and competition for access thereto matters of increasingly vital concern both to economic and to military policy makers. Competition increased the royalties of conceding states. Wherever the concessionaire's return depends upon finding oil, the risks may be considerable. The 1958 contract between Pan American Petroleum corporation (wholly owned by Standard Oil Company [Indiana]), Iran and the government-owned National Iranian Oil company required a bonus of \$25,000,000, deductible in ten equal installments, in determining taxable net profits after the start of production. Additional requirements were an annual rental of \$400-\$600 per square kilometre, an expenditure of a minimum of \$82,000,000 for exploration during the first 12 years, an income tax of 50% of net profits and an equal division of the other 50% with the National Iranian Oil company.

Venezuela's petroleum mineral law of 1943, based on state

ownership of the subsoil traceable to statutes of 1783, allowed concessions for exploration, exploitation, transportation and refining of petroleum. An exploration concession granted the exclusive right to explore for three years a specified area of approximately 10,000 ha. One-half the plot could be sold for exploitation; the remainder was to revert to the state. The exploitation concession extended for 40 years and was granted on the basis of sealed bids for specified plots. The Venezuelan arrangements led by 1952 to foreign-exchange earnings from oil of about \$500,000,000, which at that time amounted to about 50% of the country's foreign-exchange earnings and 60% of the government's revenue.

**The Nature of Concession Contracts.**—A concession contract is not made under legal compulsion but at the absolute discretion of the conceding state. Without the element of discretion the grant is not in the strict sense a concession. Employment of political and other indirect pressures need not invalidate a concession, provided that the requirements of the laws of the conceding state have been met. The concession contract grants economic rights, usually short of ownership, either for a specified time or in perpetuity. The grantor may be a unitary state or a subordinate unit such as a municipality or a native chief. The rights granted need not include a monopoly. They may include auxiliary rights such as those granted by Liberia to the Firestone Tire and Rubber company in 1926: (1) to build and use roads, bridges, airfields, pipelines, telephone lines, railroad stations, hydroelectric facilities and power lines; (2) to use public highways, public transportation and harbour facilities; (3) to import supplies and equipment duty free; (4) to construct and operate a transatlantic radio transmitter.

The concessionaire takes upon itself obligations to provide stipulated facilities such as housing or perhaps a complete village for employees. The Burmah-Shell agreement of 1951 with India for the construction of a refinery at Bombay called for a payment of \$800,000 to Bombay state for housing. Concession agreements often impose an obligation to employ citizens of the conceding state and limit the number of aliens employable. The Iranian consortium agreement of 1954 between the government of Iran, the National Iranian Oil company and eight international oil companies, including the Anglo-Iranian Oil company, required the training and education of local personnel. The concessionaire may also undertake to promote local private enterprise in the manner of the Arabian American Oil company's industrial development division, which reported a steady increase in payments to Arab contractors. As in the 1951 agreement between Standard-Vacuum Oil company and India, provisions may be made for investment by citizens of the conceding state.

A concession agreement may declare the company's insulation from domestic politics in return for abstention from participation in local politics. Provision is generally made for arbitration of disputes by a tribunal specified in the contract. Arbitration aids in adjusting a contract to changed conditions such as the extension of national jurisdiction over the continental shelf.

The concession contract declares what law governs it. For example, under the Suez concession agreement, questions of the status and internal affairs of the company were to be governed by French law applicable to joint-stock companies and to be submitted to arbitrators in France subject to appeal "to the imperial court in Paris." Disputes in Egypt between the company and third parties and those between the company and the Egyptian government were to be governed by local law applied by local tribunals. Where all parties were foreigners, litigation was to be conducted "according to established rules." Latin-American contracts regularly contain a Calvo clause impressing upon the concessionaire the capacity of a citizen or local corporation in respect to disputes. The Iranian consortium agreement declared the agreement to be governed by the principles of law common to Iran and the companies' home states and by "principles of law recognized by civilized nations in general."

**Royalties.**—Older royalty arrangements often required a fixed payment per barrel or ton produced or a lower percentage of profits than was customary after 1945. The Anglo-Persian Oil

company once paid Iran 16% of net profits plus £3,000 per annum. Fixed royalty payments often disappointed the conceding state when increased prices spelled increased corporate profits. More satisfying was the 50-50 arrangement that became common after World War II, particularly in respect to oil concessions. This arrangement allowed the state to impose a tax on the net income in such amount as would give the state 50% of the profits when added to fixed payments, if any.

A 75-25 allocation was initiated in 1957 when Ente Nazionale Idrocarburi, an Italian government corporation, undertook to purchase exploration expenses over 8,800 sq. mi. in Iran, subject to 50% retroactive reimbursement after commercial quantities of oil were found, and to accord 50% of the profits to the Iranian government and 25% to the National Iranian Oil company, which shared exploitation expenses. There was no bonus as in the Pan American Petroleum corporation contract previously mentioned. In 1958 the Japanese Arabia Oil company contracted with Kuwait for exploration and development of the area in the neutral zone between Kuwait and Saudi Arabia lying between six miles beyond low-water mark and the international boundary in the Persian gulf. Kuwait was accorded a \$1,500,000 annual rental, an additional \$1,000,000 annually from the time oil might be struck, a bonus of \$5,000,000 when production reached 50,000 bbl. daily and 57% of net profits down to the retailer. A corresponding agreement according Saudi Arabia 56% of the profits had been concluded late in 1957.

**Termination of Concessions.**—Concessions not in perpetuity end at the time set in the contract. India's agreement of 1951 with Standard-Vacuum for construction and operation of a Bombay refinery included a 25-year guarantee against nationalization.

The conceding state may, according to the terms of the concession itself, legally terminate a concession before its expiration date or, unless under treaty obligation to the concessionaire's state, by proper exercise of the right of eminent domain involving adequate compensation. Several international arbitral decisions have declared that the arbitrary employment of sovereign power, either by legislative or executive act, to annul a concession constitutes a "denial of justice" and creates an international liability to the concessionaire's state. Refusal to submit the validity of such termination to arbitration in violation of an arbitration clause has been held to create liability to make reparation. Failure to realize expected profits is not sufficient reason for releasing a state from its contractual obligations. Nor is the fact that a new state has succeeded the grantor of the concession sufficient ground for annulment by the successor state. The principle of unjust enrichment may be pleaded against the action of a successor state that ignores an expenditure of capital and labour from which the successor derives benefits.

Similarly, the principle of unjust enrichment opposes nationalization of concessionary enterprises without compensation. Nationalization of the Suez Canal company included an undertaking to compensate. The requirement of just compensation was also recognized in Mexico's settlements with the United States and the United Kingdom for its expropriation of oil lands. Even such Communist countries as Czechoslovakia, Poland and Yugoslavia conceded the necessity of compensation in their agreements with such states as France, Switzerland and the United Kingdom. In short, a concession contract involves mutual obligations not to be avoided by unilateral action.

**CONCILIATION IN INDUSTRIAL RELATIONS**  
see INDUSTRIAL RELATIONS.

**CONCLAVE** (from Lat. *cum*, "together," and *clavis*, "key," originally meaning a room or apartment locked with a key, in the

Roman Catholic Church is the specific name for the assembly of cardinals met to elect a new pope and for the system of strict seclusion to which they are submitted.

In early times, the method of episcopal election at Rome was the same as in other towns; the Roman clergy and people and the neighbouring bishops each took part in it in their several capacities. The people would signify their approbation or disapprobation of the candidates more or less tumultuously, while the clergy were, in a strict sense, the electoral body, met to elect for themselves a new head, with the bishops acting as presidents of the assembly and judges of the election. In such an assembly, the various functions were not very distinct, and persons of importance, whether clerical or lay, were bound to influence the result, sometimes decisively. Moreover, this form of election lent itself to cabals and to disputes, sometimes involving bloodshed and schisms through the election of antipopes. The remedy for this abuse was found in recourse to the support of the civil power.

It thus soon came to be accepted that the elected candidate should not receive episcopal consecration until he had obtained the confirmation of the emperor; and this state of affairs lasted almost without interruption till the middle of the 11th century. When the emperors were at Rome, they presided over the elections; when they were away, rival factions of barons struggled for the spiritual power as they did for the temporal. Cases were seen of popes imposed by a faction rather than elected and then deposed, poisoned or thrown into prison, sometimes to be restored by force of arms. After Clement II's death delegates of the Roman clergy actually asked the emperor Henry III to give them a pope, and similar steps were taken after the death of Damasus II. Fortunately on this occasion Henry appointed a man of high character, his cousin Bruno, bishop of Toul, who presented himself in Rome in company with Hildebrand (later pope as Gregory VII).

From this time began the reform. Hildebrand had the election of Victor II (1055), of Stephen X (IX) (1057) and of Nicholas II (1058) carried out according to the canonical form, including the imperial ratification. Then Nicholas issued his celebrated bull of April 13, 1059, to determine the electoral procedure. The election was reserved to the members of the higher clergy, that is, to the cardinals (*see* CARDINAL), among whom the cardinal bishops had the preponderating position. The consent of the rest of the clergy and the people was now only a formality, and the emperor was reckoned to have no rights save those he had received as a concession from the Holy See. Further, in the event of disturbances at Rome preventing the election from being carried out freely there, the cardinal bishops, together with a small number of the clergy and of the laity, were empowered to hold the election where they should think fit; and should difficulties of any sort prevent the enthronement of the new pope, he was empowered immediately to act as if he were actually pope. This legislation was accepted by the emperor Henry V by the concordat of Worms (1122).

Two other points were established by Alexander III at the Lateran council of 1179: the constitution *Licet de vitanda discordia* makes all the cardinals equally electors, omits to mention the lower clergy or the people, and requires a majority of two-thirds of the votes to decide an election.

**Institution of the Conclave.**—Abuses nevertheless arose. An electoral college too small in numbers, which no higher power has the right of forcing to haste, can prolong disagreements and draw out the course of the election. When, after the death of Clement IV in 1268, the 17 cardinals assembled at Viterbo had allowed two years to pass without coming to an agreement, the local magistrates had recourse to the method of seclusion, shutting up the electors in the episcopal palace and blocking all outlets; and when the election still delayed, the people removed the roof of the palace and allowed nothing but bread and water to be sent in. Under such pressure, the cardinals finally elected Gregory X, after an interregnum of two years, nine months and two days.

Taught by experience, the new pope considered how to prevent the recurrence of such abuses. In 1274, at the council of Lyons, he promulgated the constitution *Ubi periculum*, the substance of which was as follows: at the death of the pope, the cardinals present

are to await their absent colleagues for ten days. They are then to meet in one of the papal palaces in a closed conclave; none of them is to have more than one servant to wait on him, or two at most if he is ill. In the conclave they are to lead a life in common, not even having separate cells. They are to have no communication with the outer world; food is to be supplied to them through a window that must be under guard. The election is to be the sole business of the conclave, the magistrates of the town where it is held being required to see that these provisions are observed. Adrian V and John XXI were weak enough to suspend the constitution *Ubi periculum*, whereupon abuses at once reappeared; then Celestine V, who was elected after a vacancy of more than two years, revived it before abdicating the pontificate, and it was inserted in the decretals.

**Later Legislation.**—Pius IV's bull *In eligendis* (Oct. 1, 1562), signed by all the cardinals, is particularly notable for its regulation of the method of voting. Every day there is to be a scrutiny, or solemn voting, at which the cardinals are to use special papers (concealing the name of the voter, which is to be read only when some candidate has the required majority). This is to be followed by the *accessit*, or a second voting, at which the cardinals may transfer their suffrage to the candidates who won most votes in the scrutiny. The same bull also reaffirmed earlier measures on the question of seclusion and provided that the functionaries of the conclave were to be elected by secret ballot of the Sacred College and that the cardinals' cells were to be assigned by lot.

Something must be said about the so-called right of veto or exclusion, whereby the rulers of the various Catholic countries eventually claimed to be able to exclude from eligibility to the papacy any candidate to whom they objected. It had of course long been their practice to instruct the cardinals of their nation to do their utmost to eliminate distasteful candidatures; and they might even make public their desire to exclude certain candidates. In the course of the 16th century, however, they advanced a claim to an actual right of formal and direct exclusion, which should be notified in the conclave in their name by a cardinal charged with this mission and should have a decisive effect; and this was tacitly admitted by the Sacred College. It was a right based on custom and not supported by any written concession, but it was straightforward and definite. During the 19th century Austria exercised, or tried to exercise, the right of veto at all the conclaves, except that which elected Leo XIII (1878). Finally, in 1903, on Aug. 2, when Cardinal Rampolla had received 29 votes, Cardinal Puzyna, bishop of Cracow, declared that Austria opposed his election; whereupon the Sacred College yielded and, on Aug. 4, elected Cardinal Sarto (Pius X). Then, by the bull *Commissum nobis* (Jan. 20, 1904), Pius X suppressed all right of exclusion on the part of the secular governments and forbade, under pain of excommunication reserved to the future pope, any cardinal or conclavist to accept from his government the charge of proposing a veto, or to exhibit it to the conclave under any form.

Meanwhile Leo XIII's constitution *Praedecessores nostri* (May 24, 1882) had authorized occasional derogations from established order in circumstances of difficulty, such as the death of a pope elsewhere than in Rome or attempts to interfere with the liberty of the cardinals. This constitution was left untouched when Pius X issued his constitution *Vacante sede apostolica* (Dec. 25, 1904), which superseded all other legislation on the conclave. *Vacante sede apostolica* was a codification rather than a reform, its principal innovation being the abolition of the *accessit* and the substitution of a second ordinary scrutiny during the same session. Pius XII's constitution *Vacantis apostolicae sedis* (Dec. 8, 1945) modified the effect both of *Praedecessores nostri* and of *Vacante sede apostolica* and increased the requisite majority for the election of a pope from two-thirds of the votes cast to two-thirds plus one.

**Procedure.**—On the death of the pope, the cardinal camerlengo of the Holy Roman Church, who is the personal representative of the Sacred College in the ordinary administration, takes up residence in the Vatican palace; and wherever he goes in the palace he is escorted by the Swiss guards. Every morning, from the death of the pope to the beginning of the conclave, all the cardinals meet

in the hall of the Consistorium to hold a congregation; that is to say, to consult on current business. Assembled in that hall they receive the condolences of the diplomatic corps and of the Knights of Malta. The general congregation deals with the most important business; and a special congregation (the senior cardinal bishop, the senior cardinal priest and the senior cardinal deacon, with the cardinal camerlengo) meets daily to transact affairs of minor importance. At the first general congregation the seals of the deceased pope (the Fisherman's ring and the leaden seal of the Apostolic chancery) are handed over to the Sacred College and are at once broken. On nine consecutive days the obsequies of the pope (the *novendialia*) are celebrated in the Basilica of St. Peter's. At the last service the funeral sermon is preached.

The cardinals used to enter into conclave one day after the *novendialia*. In order, however, to give the cardinals from distant parts of the world time to reach Rome, Pius XI increased the interval between the death of the pope and the entry into conclave to 18 days. On the morning of the day on which they go into conclave, the cardinals meet in the Pauline chapel to hear the Mass of the Holy Spirit celebrated by the cardinal dean and to listen to a sermon preached by a prelate on the election of the pope.

From the beginning to the end of the conclave that part of the Vatican palace which is reserved to it is closed to outsiders, and the doors giving access to it from the outside are walled up. The walls, however, are pierced by rotas or turning-boxes, through which it is possible to pass objects without seeing the recipient and to converse provided that the voice is raised. The guardianship of the rotas is entrusted to prelates, who decide in what cases persons may be authorized to converse with the cardinals, are present at such conversations and inspect all objects which it is desired to introduce into the conclave. The conclave is guarded from the outside by the marshal of the Holy Roman Church and by one of the palatine prelates. Within the palace are only the cardinals with their secretaries or "conclavists," the masters of the ceremonies, certain other ecclesiastics with definite duties, doctors and the service staff. All matters connected with the conclave are directed by the secretary of the Sacred College and the prefect of papal ceremonies. The admission of anyone who is to reside within the precincts of the conclave must be approved in advance by the general congregation of cardinals. The interior of the palace is divided into small apartments (*cellae*), one for each cardinal, assigned by lot.

Every day the cardinals proceed to the Sistine chapel, for their double vote. Within this chapel, along the lateral walls, small thrones are arranged, each surmounted by a violet-coloured canopy, one for each cardinal. Each vote is immediately counted by three scrutineers, elected at each morning and each afternoon session in such a way that they are never the same, minute precautions being taken to ensure that the voting shall be secret and sincere. Immediately after the count, the voting papers are burned in a stove in a corner of the chapel, and the smoke, passing up an iron pipe through a window, enables the crowd assembled on the piazza of St. Peter's to guess how the voting has gone: when no candidate receives the requisite majority of two-thirds plus one, the votes are burned with wet straw so that the smoke shows black; when a pope is elected, the votes are mixed with dry straw so that the smoke is white. When one cardinal has at last obtained the requisite majority, the cardinal dean formally asks him whether he accepts his election and what name he wishes to assume. The canopies are removed from all the thrones save that of the cardinal who has been elected pope. On his accepting the pontificate, the news is announced to the assembled populace by the senior cardinal deacon from the central balcony in the façade of St. Peter's. Soon afterward the new pope himself, wearing the pontifical robes (for before the first vote took place three sets of robes of different sizes were placed in readiness in a cabinet adjoining the Sistine chapel), appears at the same balcony and gives his first benediction to the crowd assembled on the piazza. On the day that the election has taken place the cardinals leave the conclave, which comes to an end with the election.

The coronation of the new pope takes place a few days later, the day being fixed by the pope himself. If the new pope does not

possess episcopal rank the privilege of consecrating him belongs to the cardinal bishop of Ostia.

**CONCORD**, a city in Contra Costa county near Mt. Diablo, California, U.S., 20 mi. E. of Oakland and 30 mi. from San Francisco, is primarily residential. Many citizens commute to work in the industrialized cities of Antioch, Pittsburg, Martinez and Port Chicago.

Under the Spanish Dons, cattle grazed the region. Later, when orchards and vineyards predominated in the valley, Salvador Pacheco built the first house in 1853. The city was surveyed in 1869 and incorporated in 1905. A council-manager form of government was established in 1953.

For comparative population figures see table in CALIFORNIA Population.

**CONCORD**, a town of Middlesex county, Mass., U.S., 19 mi. N.W. of Boston, was the site of the first forcible resistance to the American Revolution, immortalized as "the shot heard round the world." Situated at the confluence of two streams forming the Concord river, Concord was founded in 1635, the first town above the fall line on the New England frontier. Simon Willard, one of its founders, was a fur trader and the early economy centered on fur trade and cattle raising.

In 1774 the first county convention to denounce the "Coercion acts" depriving Massachusetts of its charter and the right to choose its own magistrates met in Concord. The first and second provincial congresses defied British authorities there. To destroy arms and ammunition, the British army occupied the town on April 19, 1775. Forewarned, citizens had removed most of the supplies. The British who crossed the river at North bridge were driven back by minute men. This action opened the military phase of the American Revolution.

Nineteenth-century Concord became a cultural centre. Transcendentalist philosopher Ralph Waldo Emerson, naturalist Henry Thoreau, novelist Nathaniel Hawthorne, sculptor Daniel Chester French, A. Bronson Alcott and his daughter Louisa May (author of *Little Women*) and others lived there. From 1879 to 1887 the summer School of Philosophy begun by Bronson Alcott met. The Industrial Revolution brought the railroad, which undermined Concord as a trading centre and led to the development of dairy and fruit growing. Around 1850 Ephraim Bull perfected the Concord grape, marking the beginning of the cultivation of table grapes in the U.S. on a commercial scale. The rapid influx of commuters after 1950 necessitated the establishment of the selectmen-manager form of government in 1956.

Historic sites include French's "The Minute Man" statue at North bridge, Revolutionary buildings, the homes of Emerson, Hawthorne, the Alcotts and others, Walden pond, the cemetery and the Antiquarian Society's museum.

For comparative population figures see table in MASSACHUSETTS Population.

See Austin Warren, "The Concord School of Philosophy," *New England Quarterly*, II, pp. 199-233 (April 1929).

**CONCORD**, capital of New Hampshire, U.S., seat of Merrimack county, on the Merrimack river, is near the centre of the southern part of the state. The site was granted by the Colony of Massachusetts Bay in 1726 as Pennycook plantation. At that time the colony, which claimed rightfully to a point 3 mi. N. of the lower Merrimack river, assumed to project this line, 3 mi. from the left bank, along the north-south course of the upper river to Lake Winnepesaukee. Consequently the grant of 1726 lay astride the river, as the city does today. Settled in 1727, the community's name soon became Rumford, when Benjamin Thompson, resident of the town for a few years before the American Revolution, took the title of Count Rumford.

In 1741 it was determined that the town was within the jurisdiction of the Province of New Hampshire, which had granted townships whose lines fell within the bounds of the old plantation. Boundary litigation ended in an appeal to the privy council in London, where the inhabitants of Rumford were successful. The town was named Concord in 1765.

New Hampshire's legislature, after 1775, moved from place to place until 1808, when, after experimental sessions at Concord,

it settled there. In 1823 Merrimack county was organized from parts of other counties, and Concord became the county seat.

In the early 19th century the principal nonagricultural industry was printing. Carriage making and the Concord coach, famed for its use in cross-country stage coach travel, soon challenged the older industry, as did the production of granite. The railroads and car-repair shops took predominance at the end of the century. Meanwhile the manufacture of sterling silverware had become important, but it faded and died before 1950. With the mid-20th century decline of railroads, printing was again the chief single industry, with tanning and leather goods in second place. The state government was the largest employer. Small industries included the manufacture of electric and electronic equipment. Businesses included banks and a life and accident insurance company and a farm bureau mutual fire and casualty company.

The well-known St. Paul's school for boys (Protestant Episcopal, 1853) is 2 mi. W. of the city.

Chartered as a city in 1853, the government shifted from a council and weak mayor (1853–1950) to a city manager and council (1950–58), and to a strong mayor and council in 1958.

For comparative population figures see table in NEW HAMPSHIRE: Population. (E. L. PA.)

**CONCORD, BOOK OF** (Lat. *concordia*, "agreement"), the collected doctrinal standards of the Lutheran Church. It consists of (1) a preface signed by 51 electors, bishops, princes and nobles of the Holy Roman empire and representatives of 35 free cities; (2) the three Catholic Creeds (the so-called Apostles', Nicene and Athanasian); (3) the "unaltered" Augsburg Confession (1530) and (4) its Apology (1531); (5) the Schmalkald articles (1536–37); (6) Philipp Melancthon's *Tractate on the Authority and Primacy of the Pope* (1537); (7) Martin Luther's Small and Large Catechisms (1529) (see CATECHISM); (8) the Formula of Concord, consisting of an "epitome" and a "solid declaration" (1577); and the Catalogue of Testimonies (1580), an optional supplement of patristic citations.

The authoritative German edition was published June 25, 1580, the 50th anniversary of the presentation of the Augsburg Confession; the authoritative Latin translation followed in 1584. The issuance of the Book of Concord represented the climax of 30 years of effort to heal the schisms that had broken out in the Lutheran movement after Luther's death and to keep the Lutheran churches from being absorbed into a pan-Protestant union. After two political conferences (Frankfurt am Main, 1558; Naumburg, 1561) had failed, the princes concerned entrusted the project to theologians, among them Jakob Andreä of Tübingen, Martin Chemnitz, Nikolaus Selnecker of Wolfenbüttel, David Chyträus of Rostock and Andreas Musculus and Christoph Corner of Frankfurt an der Oder. These six theologians produced the Formula of Concord.

Although the Book of Concord was not everywhere adopted in its totality (churches in the Danish-Norwegian tradition, for instance, receive only the Catholic Creeds, the Augsburg Confession and the Small Catechism), its formulations have remained the standard of orthodox Lutheran theology. In committing themselves to the Book of Concord, Lutheran churches and clergymen accept the pre-eminent authority of the Catholic Creeds and receive the Augsburg Confession as the decisive Lutheran particular creed; the remainder of the Book of Concord is regarded as an explication of the Augsburg Confession.

A critical German and Latin text, with extensive bibliographies, may be found in Hans Lietzmann (ed.), *Die Bekenntnisschriften der evangelisch-lutherischen Kirche herausgegeben im Gedenkjahr der Augsburschen Konfession 1930*, 4th ed. (1959). A modern English version is Theodore G. Tappert (ed.), *The Book of Concord* (1959).

(1956); Edmund Schlögl, *Theology of the Lutheran Confessions*, Eng. trans. by Paul F. Koehnke and Herbert J. A. Bouman (1961). (A. C. PN.)

**CONCORDANCE**, literally, "agreement," "harmony"; hence

derivatively a citation of parallel passages, and specifically an alphabetical arrangement of the words contained in a book with citations of the passages in which they occur. Concordances in this last sense were first made for the Bible, and though they also have been prepared for secular literature (particularly the works of Shakespeare), it is in connection with the Bible that the word is used most often.

The original impetus to the making of concordances was due to the conviction that the several parts of the Bible are consistent with each other, as parts of a divine revelation. To Anthony of Padua tradition ascribed the first concordance, the anonymous *Concordantie Morales*, of which the basis was the Vulgate Bible. The first authentic Latin concordance to the Vulgate was due to Hugh of St. Cher, a Dominican monk (d. 1264), who, in preparing for a commentary on the Scriptures, found the need of a concordance. This, the *Concordantie Sacrorum Bibliorum* (or *Sancti Jacobi*), in the compilation of which Hugh was assisted by others of his order, became the basis of one by Conrad of Halberstadt (c. 1290) and of another by John of Segovia in the next century. The concordance to the Vulgate in modern use is based on one by F. P. Dutripon (1838).

The first Hebrew concordance was compiled in 1437–45 by Rabbi Isaac Nathan ben Kalonymus of Arles and printed at Venice in 1523. Its errors were corrected by Mario di Calasio, a Franciscan friar, who published an edition at Rome in 1621, much enlarged, with proper names included. Another concordance based on Nathan's was that of Johannes Buxtorf the elder (1632), several times revised and republished. The standard modern concordance to the Hebrew Old Testament is that by Solomon Mandelkern (1925); an excellent later one is that of Gerhard Lisowsky (1955–58).

A *Concordance to the Septuagint* was published at Frankfurt in 1607. The still standard *Concordance to the Septuagint and the Other Greek Versions of the Old Testament Including the Apocryphal Books*, by Edwin Hatch and H. A. Redpath, assisted by other scholars, was published in 1897 and completed in 1900 by a list of proper names.

A concordance to the Greek New Testament, published in 1638 by Erasmus Schmied or Schmid, has been the basis of other subsequent concordances, including a well-known edition by B. F. Westcott and F. J. A. Hort, with readings of S. P. Tregelles, in 1888. The standard work is the *Concordance to the Greek Testament*, edited by W. F. Moulton and A. S. Geden (1897).

The first concordance to the English New Testament was published in London, in 1535, by Thomas Gybson, the first to the entire English Bible by John Marbeck in 1550. They were followed by many others. Then, in 1737, Alexander Cruden (q.v.) published his *Complete Concordance to the Holy Scriptures of the Old and New Testament, to Which Is Added a Concordance to the Books Called Apocrypha*, which surpassed all its predecessors. Three editions were published during Cruden's life, and many since his death. Later concordances supersede his notably accurate work only by combining an English with a Greek and Hebrew concordance. Among late-19th- and 20th-century concordances to English translations of the Bible are R. Young's (1879); J. Strong's, to the Revised Version (1894); M. C. Hazard's, to the American Standard Version (1922); W. J. Grant's, to the Moffatt translation (1950); and that supervised by John W. Ellison, to the Revised Standard Version (1957).

**CONCORDAT**, a term originally denoting an agreement between ecclesiastical persons or secular persons but later applied to a pact concluded between the ecclesiastical authority and the secular authority on ecclesiastical matters that concern both, and, more specially, to a pact concluded between the pope, as head of the Roman Catholic Church, and a temporal head of state for the regulation of ecclesiastical affairs in the territory of the latter. It is to concordats in this second sense that this article refers.

For the purposes of a concordat the state recognizes the official status of the church and of its ministers and tribunals, guarantees it certain privileges, etc. The pope on his side grants the temporal state certain rights, such as that of appointing or controlling the appointment of dignitaries; engages to proceed in harmony with the government in the creation of dioceses or parishes; etc. The

great advantage of concordats—indeed their principal utility—consists in transforming necessarily unequal unilateral claims into contractual obligations analogous to those that result from an international convention. Whatever the obligations of the state toward the ecclesiastical society may be in pure theory, in practice they become more precise and stable when they assume the nature of a bilateral convention by which the state engages itself with regard to a third party. And reciprocally, whatever may be the absolute rights of the ecclesiastical society over the appointment of its dignitaries, the administration of its property and the government of its adherents, the exercise of these rights is limited and restricted by the stable engagements and concessions of the concordatory pact, which bind the head of the church with regard to the nations.

Concordats have therefore the perpetuity of conventions that contain no time limitation; but, like every human convention, they can be denounced. Though there is no example of a concordat having been denounced or broken by the popes, several have been denounced or broken by the civil powers, sometimes in the least diplomatic manner.

The rupture of the concordat at once terminates the obligations that resulted from it on both sides, though it does not break off all relation between the church and the state, since the two societies continue to coexist on the same territory.

**Objects of Concordatory Conventions.**—These cannot be described in detail, since they are concerned with extremely varied matters. In the first place there is the official recognition by the state of the Roman Catholic religion and its ministers. Sometimes the Catholic religion is declared to be the state religion, and at least the free and public exercise of its worship is guaranteed. As regards candidates for ecclesiastical offices, the concordats concluded with Catholic nations regularly give the sovereign the right to nominate or present to bishoprics, often also to other inferior benefices; or at least the choice of the ecclesiastical authority is submitted to the approval of the civil power. In all cases canonical institution (which confers ecclesiastical jurisdiction) is reserved to the pope or the bishops. In countries where the head of the state is not a Catholic, the bishops are regularly elected by the chapters, but the civil power has the right to strike out objectionable names from the list of candidates that is previously submitted to it.

Certain concordats deal with the orders and congregations of monks and nuns with a view to subjecting them to a certain control while securing to them the legal exercise of their activities. Ecclesiastical immunities, such as reservation of the criminal cases of the clergy, exemption from military service and other privileges, are expressly maintained in a certain number of pacts. One of the most important subjects is that of church property. An agreement is come to as to the conditions on which pious foundations are able to be made; the measure in which church property shall contribute to the public expenses is indicated; etc.

**Concordats in History.**—The earliest concordats were associated with the investiture controversy (*q.v.*) that so profoundly agitated Christian Europe in the 11th and 12th centuries. The first in date is that concluded for England with Henry I in 1107 by the efforts of St. Anselm. The convention of Sutri of 1111 between Pope Paschal II and the emperor Henry V having been rejected, negotiations were resumed by Pope Calixtus II and ended in the concordat of Worms (1122), which was confirmed in 1177 by the convention between Alexander III and the emperor Frederick I. In this concordat the emperor renounced spiritual investiture and permitted canonical elections; the pope on his part recognized the king's right to perform lay investiture and to assist at elections. Analogous to this convention was the concordat concluded between Nicholas IV and the king of Portugal in 1289.

The lengthy discussions on ecclesiastical benefices in Germany ended finally in the concordat of Vienna, promulgated by Nicholas V in 1448. Already at the Council of Constance (1414-18) attempts had been made to reduce the excessive papal reservations and taxes in the matter of benefices, privileges that had been established under the Avignon popes and during the Great Schism.

The Council of Basel went further; it suppressed annates and all the benefice reservations that did not appear in the *Corpus Juris*. Eugenius IV repudiated the Basel decrees, and the negotiations terminated in what was called the "concordat of the princes," which was accepted by Eugenius IV on his deathbed (1447). In Feb. 1448 Nicholas V concluded the arrangement, which took the name of the concordat of Vienna. This concordat, however, was not received as law of the empire. In Germany the concessions made to the pope and the reservations maintained by him in the matter of taxes and benefices were deemed excessive, and the prolonged discontent that resulted was one of the causes of the success of the Lutheran Reformation.

In France the opposition to the papal exactions had been still more marked. In 1438 the pragmatic sanction of Bourges adopted and put into practice the Basel decrees, and in spite of the incessant protests of the Holy See the sanction was observed throughout the 15th century, even after its nominal abolition by Louis XI in 1461.

The situation was modified by the concordat of Bologna, which was personally negotiated by Pope Leo X and Francis I of France at Bologna in Dec. 1515, inserted in the bull *Primitiva* (1516) and promulgated as law of the realm in 1517, though not without rousing keen opposition. All bishoprics, abbeys and priories were in the royal nomination, the canonical institution belonging to the pope. The pope preserved the right to nominate to vacant benefices *in curia* and to certain benefices of the chapter, but all the others were in the nomination of the bishops or other inferior collators. However, the exercise of the pope's right of provision still left considerable scope for papal intervention, and the pope retained the annates.

The concordats drawn up during the 17th and 18th centuries either fell to the ground or had to be recast. In the 19th century was concluded a long series of concordats, of which a good number remain in force. The first in date and importance is that of 1801, concluded for France between Napoleon and Pius VII after laborious negotiations. The first consul was given the right to nominate bishops, the bishoprics and parishes were redistributed and the erection of seminaries allowed. The pope condoned those who had acquired church property; and by way of compensation the government engaged to give the bishops and *curés* suitable salaries. The concordat was solemnly promulgated on Easter day 1802, but the government had added to it unilateral provisions of Gallican tendencies, which were known as the Organic articles. After having been the law of the church of France for a century, it was denounced by the French government in 1905, when by the "separation law" church and state were sundered.

A concordat with England was proposed by Castlereagh in 1814, but the negotiations broke down over the question of episcopal nominations. Other important concordats were concluded during the 19th century with Germany, Bavaria (1817), Prussia (1821), Hanover (1824), Austria (1855; denounced by the Austrian government on the proclamation of papal infallibility in 1870), Spain (1851, 1855, 1904), Switzerland (1828, 1845, 1888) and Portugal (1857, 1886). In the case of Russia, a formal concordat was found inapplicable even as far back as 1847. In the case of Holland and Belgium, concordats were replaced by an amicable *modus vivendi*.

During the 20th century important new concordats were made, the most important being those with Poland (1925), Lithuania and Rumania (1927), Italy (1929; the so-called Lateran treaty which recognized papal sovereignty over the Vatican city-state), Spain (1933), Yugoslavia (1935), Portugal (1940), Spain (1953; reconfirming Spanish loyalty to the church after the abrogation of the previous concordat by the republican government in 1931) and the Dominican Republic (1954).

**CONCRETE (IN PHILOSOPHY).** Roughly, such things as numbers, classes, states, qualities and relations are called abstract, while persons, physical things and events are concrete. Logicians have traditionally classified terms or names as being abstract or concrete according as they are intended to denote abstract or concrete things. Many, however, add a third category of collective names; *i.e.*, names of classes or collections of concrete things, distinct from the category of abstract names. See **ABSTRACT AND ABSTRACTION**; and **NAME (IN LOGIC)**.

The distinction between abstract and concrete, though clear enough in general, is not a very sharp one, and borderline cases may be found. For example, consider the series of terms *theory*, *true proposition*, *fact*, *event*, or, to turn to theoretical physics, the series *conductivity*, *speed*, *heat*, *magnetic field*, *light*, *electric charge*, *electron*, *molecule*. In each case the series begins with an abstract term, and it may be thought that the terms grow successively more concrete. Some, however, may prefer a different order as that of increasing concreteness. In any case, if an absolute separation into abstract and concrete is demanded, it becomes difficult to decide where to draw the line.

See J. S. Mill, *A System of Logic Ratiocinative and Inductive* (1884); W. V. Quine, *Methods of Logic* (1950). (Ao. C.)

**CONCRETE** is a building material consisting of a mixture in which a paste of portland cement and water binds inert aggregates into a rocklike mass as the paste hardens through chemical reaction of the cement with water. Concrete occupies a dominant position in modern construction. It is used in highways, bridges, and dams; in the construction of virtually all large buildings, sidewalks, farm structures, and homes; and in airport runways, dry docks, irrigation structures, piping, harbours, silos, and a multitude of other major and minor construction projects.

Ever since man first started to build, he has sought a material that would bind sand and stones into a solid, formed mass. The Assyrians and Babylonians used clay for this purpose, and the ancient Egyptians advanced to the discovery of lime and gypsum as a cementing agent. The Greeks made further improvements, and the Romans developed a cement by mixing slaked lime with volcanic ash. Roman cement concrete was used in construction of aqueducts, bridges, and buildings, some of which survive in an excellent state of preservation. Lime in some form remained the principal cementing material until portland cement was discovered shortly after 1800. Portland cement became the dominating cementing material used in concrete construction about 1900, and the word "concrete" without a qualifying term has since been used mainly as an abbreviation of "portland cement concrete." Limited use is also made of other cements having properties similar to portland cement, such as natural cement and blast-furnace slag cement (see **CEMENT**).

Sand, gravel, and crushed stone are common aggregates used in concrete. Clays and shales processed by heat into hard stone-like particles, natural volcanic aggregates, and cinders and processed blast-furnace slag are also used. The specific gravity of ordinary concrete is about 2.4 (150 lb. per cu.ft.); compressive strength from 1,000 to over 10,000 lb. per sq.in. (70 to more than 700 kg./cm.<sup>2</sup>) can be obtained by varying the proportions of the concrete mixture. By use of heavy stone aggregates such as barite and magnetite, dense concrete mixtures with a specific gravity of more than 4.0 can be made for shielding purposes in atomic-reactor structures. On the other hand, if light aggregates or special foaming processes are used, concrete for thermal insulation can be made so light that it will float on water, and it can be sawed and nailed like lumber. The type of concrete mixture used is determined by the purpose for which it is intended—a goldfish pool, an office floor, or a launching pad for rockets.

### TECHNOLOGY OF PLAIN CONCRETE

The technology of plain concrete is a materials engineering science; it concerns the mixing, casting, finishing, and curing of concrete—and effects of these processes on the physical and chemi-

cal properties of the material, concrete. The uses of concrete in structures, highways, etc., involve other civil engineering sciences, such as structural, highway, foundation, sanitary, and railway engineering.

**Concrete Mixtures.**—Good concrete for small jobs and minor repairs at home and on the farm can be made by amateurs. Design and construction of important concrete structures, however, is a combination of science, art, and experience; it should be undertaken only by professional persons very familiar with concrete technology.

The character of concrete is determined primarily by the quality of the cement-water paste that binds the aggregates together. If too much water is used, the paste becomes thin and will be weak when it hardens. The strength of the cement paste and ultimately the durability, strength, watertightness, and other properties of the concrete depend strongly on the amount of mixing water used. The proportions of water and cement are usually referred to as the water-cement ratio expressed as the weight of water used per unit weight of cement. The lower this ratio, so long as the concrete is workable, so long as each particle of aggregate is completely surrounded by paste and all spaces between the aggregate particles are completely filled with paste, the more durable and strong will be the concrete. Developed primarily by the U.S. engineer Duff A. Abrams, the water-cement ratio law became widely known and used about 1920. It is the basis of modern concrete technology.

For most home repairs and improvements such as floors, walks, driveways, playcourts, or garden pools, the following proportions of concrete materials should be used: 1 bag (43 kg.) of portland cement, 6 U.S. gal. of water (23 litres), and such quantities of sand and gravel or crushed stone as will result in a workable mixture—usually 2 cu.ft. (57 litres) of dry sand and 3 cu.ft. (85 litres) of gravel or crushed stone. If the sand is wet, only 5 U.S. gal. (19 litres) of mixing water should be used for each bag of cement, since 2 cu.ft. of wet sand will contain about 1 U.S. gal. of water. Any potable water is suitable to use for making concrete.

The aggregates should be clean, sound, and free from soft particles and vegetable matter. Even small quantities of the organic compounds present in topsoil will seriously retard and impair the strength-producing chemical reaction between cement and water. All sand (fine aggregate) should pass through a  $\frac{1}{2}$ -in. sieve (one with four openings to the inch). The best results are obtained when the sand is a good blend of grain sizes from  $\frac{1}{4}$  to  $\frac{1}{8}$  in. Gravel or crushed stone (coarse aggregate) should also be a blend of grain sizes from  $\frac{1}{4}$  in. up to the maximum size used. The proper maximum size of coarse aggregate depends on the thickness of the member for which the concrete is to be used. For example, pea-size coarse aggregate would be used in building garden pools or other structures with thin sections, while aggregates over six inches in diameter are used in large dams. In general, the maximum diameter of coarse aggregate should not be larger than one-fifth of the narrowest dimension of the concrete member in which it is used.

The proportions of coarse aggregate to fine aggregate, and the total amount of aggregate that can be used with a given water-cement paste, depend on the grading, shape, and size of the aggregates and also on the consistency of the concrete required. Stiff dry concretes require less paste than highly plastic mixtures. Less paste is required when aggregates are graded up to a large size than when the maximum size is small. Aggregates made up of rounded particles require less paste than rough and irregular ones such as crushed stone. Concrete mixtures are therefore designed to produce the most economical concrete meeting the various requirements of construction and service.

Although good concrete can be mixed by hand, machine mixing is preferred because it results in more thoroughly mixed and uniform batches. Mixing should always continue until every piece of aggregate is completely coated with a thoroughly mixed cement paste. After the concrete is mixed and the desired workability attained, it should be placed in the forms within 90 min. after water has been added. It should be well compacted (vibrated) during the placing process. For floors, walks, steps, and driveways, the concrete should be leveled off with a straight-edged board as

soon as it is placed, and then allowed to stand until the film of moisture disappears from the surface. It should then be smoothed off quickly with a wood float to produce a nonslippery surface. When a very smooth surface is desired, the concrete may be finished with a steel trowel after the wood float has been used. The trowel should be used sparingly and only after the concrete has become quite stiff, in order to avoid bringing an excessive amount of fine particles to the surface.

When exposed surfaces of the concrete have hardened sufficiently to resist marring, they should be sprinkled with water and protected by moisture-retaining materials such as polyethylene sheets, burlap, or moist sand. Hardening of the cement paste requires time, moisture, and favorable temperatures. The longer concrete is kept moist, therefore, the more durable and strong it will become.

Specifications governing concrete materials, proportions of concrete mixtures, methods of construction, and properties of hardened concrete are issued by the British Standards Institution, the American Society for Testing Materials, the American Concrete Institute, and by similar organizations in most other countries.

**Air-Entrained Concrete.**—The most destructive of nature's weathering forces are repeated freezing and thawing when the concrete is wet. Furthermore, the action of chloride salts applied to concrete pavements to melt ice has a tendency to disintegrate the pavement surface. Air-entrained concrete, which contains billions of microscopic air cells per cubic foot, provides tiny chambers for the expansion of freezing water so that internal pressure on the concrete is relieved. Air-entrained concrete is produced through the use of air-entraining portland cement (*see CEMENT*) or by adding an air-entraining resinous substance with the mixing water at the concrete mixer.

The amount of entrained air is usually between 4 and 7% of the concrete volume. This results in concrete that is practically immune to frost action and highly resistant to the action of salts used to melt pavement ice. Air-entrained concrete is used widely in construction of pavements, bridges, and other ex-

posed structures in cold climates. Entrained air also improves the workability and cohesiveness of fresh concrete. When such concrete is placed and compacted, there is less tendency for the ingredients to separate, and less water will rise to the surface of the fresh concrete. Better uniformity is thereby maintained throughout the concrete. Accordingly, air-entrained concrete is often used even when resistance to frost action is not required.

**Ready-Mixed Concrete.**—This concrete is produced by a manufacturer and delivered by truck to the construction site. The mixing methods used vary. In some instances the concrete is mixed completely at the manufacturer's plant, and the mixed concrete is transported to the construction site in trucks equipped to agitate the concrete during transport. In another procedure, the dry materials are weighed and batched into a truck mixer at the central plant. Water is then added and mixing is completed in transit to the construction site. Truck mixers consist essentially of a mixer with separate water tank mounted on a truck chassis. They are usually made with capacities of 1, 1½, 2, 3, 4, and 5 cu yd. For small home repairs, mixtures of dry concrete materials are available in small bags at hardware and building supply stores.

From a modest beginning in the 1920s, ready-mixed concrete became established as a construction material in the 1940s. By the 1960s well over 50% of the portland cement produced in the United States was shipped to the ready-mixed concrete industry. This industry produced annually in excess of 150,000,000 cu yd. of concrete valued at more than \$2,000,000,000.

## STRUCTURAL CONCRETE

Concrete used in buildings and bridges, known as structural concrete, is characterized by relatively thin sections as compared to the massive concrete sections used in foundations and dams. It was made possible by the development of reinforced concrete shortly before 1900, and through new techniques—such as prestressing, shells, and architectural concrete—its use as an architectural medium has been continuously improved and expanded.

**Reinforced Concrete.**—When steel bars are embedded in the concrete, the result is called reinforced concrete. Concrete is about ten times stronger in compression than in tension. When structural concrete members such as floor beams must resist large tensile stresses, steel is embedded in the concrete in the form of bars or mesh. Thus, the tensile strength of steel supplements the compressive strength of concrete, forming reinforced concrete structural members capable of sustaining heavy loads over considerable spans.

Two fundamental properties permit concrete and steel to work together as a composite material. Their coefficients of thermal expansion are approximately equal; if this were not so, reinforced concrete would tear itself apart by internal stress when subjected to wide temperature changes. Secondly, the cement paste in concrete bonds strongly to the steel bars, transferring stress from concrete to steel and protecting the steel against corrosion. In bridge girders spanning a single opening between two abutments, reinforcing bars are placed near the lower side, as that is the side subject to tensile stress when the beam is loaded by the weight of the bridge itself and crossing vehicles. In some cases, such as fence posts, light poles, and chimneys, the load may come from any direction. It is then necessary to reinforce all portions that may be subject to tensile stress. Long beams (such as those supporting the floor of a warehouse) extending continuously over a number of columns may be subjected to tension on the upper side near intermediate column supports. Steel bars referred to as negative reinforcement are then placed in the upper portion of the beam near columns. Between column supports, bars referred to as positive reinforcement are placed in the lower portion of the beams to resist tensile stress in a manner similar to that of the single-span beam. Where space limits the size of structural members and loads are such that concrete alone is not adequate, steel bars are used as reinforcement to increase the compressive strength of members. Finally, steel bars are used to increase shearing strength and to prevent cracking that would otherwise result from wide temperature changes.

Reinforced concrete has become one of the mainstays of modern

CROSS SECTIONS OF HARDENED CONCRETE

construction. Not only is it economically competitive with steel frame construction, but its advantageous properties have had a radical effect on architectural design.

The first clear record of an attempt to use reinforcement in concrete was an experimental arch built in 1832 by Sir Marc Isambard Brunel in connection with his construction of a tunnel under the Thames River at London. Other experiments soon after this time suggest that the idea of using steel or iron to withstand tension in concrete was not developed by a single mind, but was rather the product of a period marked by the use of iron as a structural material. While Joseph Louis Lambot built a small rowboat of reinforced concrete in 1849, and François Coignet is believed to have obtained his first patent for reinforced concrete construction in 1855, the discovery of reinforced concrete is usually attributed to the Parisian gardener Joseph Monier, who made garden pots and tubs of concrete reinforced with iron mesh. He obtained his first patent July 16, 1867. Among many other patents that followed was one issued in 1878 to Thaddeus Hyatt, U.S. lawyer and inventor.

The practical development of reinforced concrete was initiated in the 1880s primarily by G. A. Wayss of Berlin, François Hennebique of France, and Johann Bauschinger of Austria. Design methods based on scientific principles of engineering mechanics were developed shortly after 1900. Since that time vast improvements in reinforced concrete design and construction practice have resulted from research and experience. Indicative of the expanded usage of reinforced concrete is the fact that the production of reinforcing steel in the United States grew from a few tons in 1900 to about 2,500,000 tons by the 1960s, as reinforced concrete became widely used, not only for building and bridge construction but for a variety of purposes ranging from fence posts to the largest and most complex civil engineering projects.

Specifications governing the principles and methods of design for reinforced concrete are issued by the American Concrete Institute, by the British Standards Institution, and by standards associations or government departments of public works in most other countries.

**Prestressed Concrete.**—Reinforced concrete that has been placed in a state of permanent precompression before service loads are applied is called prestressed concrete. This is commonly done by tensioning high-strength steel wire or rods used as reinforcement. Prestressing extends previous limitations on the spans and loads for which a concrete structure can be economically designed. It permits construction of concrete bridges, roofs, floors, and other structural members of longer free spans; it enables engineers and architects to design and build lighter, shallower, and more graceful concrete structures without sacrificing strength; and it permits construction of thin-walled concrete pipe and tanks able to resist great internal pressure without leakage. Prestressed concrete does not replace conventional reinforced concrete. When spans are so great or loads so heavy as to make the use of reinforced concrete impractical, prestressed concrete often provides an economical solution, but reinforced concrete continues to be widely used where the unique properties of prestressed concrete cannot be used to an economic advantage.

The basic principle of prestressing has been used for many years in the manufacture of wagon wheels. The steel rim is expanded by heating before it is placed on the wooden wheel. As the rim cools, it contracts, placing itself in tension and the wood in a state of compression. Similarly, the steel hoops of a barrel place the wooden staves in precompression. The precompression introduced by tensioned steel contributes importantly to the strength and resiliency of both wheel and barrel. This analogy is particularly striking for large prestressed concrete pressure vessels used for containment in atomic power plants.

The strengthening compressive stresses are usually induced in prestressed concrete by either pretensioning or posttensioning. In the pretensioning process, the steel is stretched between two abutments before the concrete is placed. After the concrete has hardened around the tensioned reinforcement located in the lower portion of beams and slabs, the stretching forces are released. Then, as the steel seeks to regain its original length, tensile stress in the

steel is translated into compressive stress in the concrete by bond between steel and concrete. This process is easily adaptable to mass-production methods and is widely used in large factories. In the posttensioning process, steel cables are located in ducts embedded in the concrete. The steel is stretched by hydraulic rams after the concrete has hardened and is fastened externally by wedges or other gripping devices. In this process, the steel is tensioned against the concrete so that tension exerted on the steel corresponds to an equal compression on the concrete. Many systems of posttensioning are in use; they differ primarily in the type of gripping devices employed.

The first patent on prestressed concrete was issued in 1888 to P. H. Jackson of San Francisco. Prestressing was attempted with little success both in the United States and in Europe. Low-strength steels were used, and the prestressing forces were lost by gradual drying shrinkage of the concrete. In 1928 the French engineer Eugène Freyssinet (*q.v.*) proved that when high-strength steel wires are used for prestressing, the shrinkage losses amount to only a few percent of the tensile force in the steel. Prestressed concrete was developed in full maturity in western Europe and in England in the 1940s; it was widely used in reconstruction after World War II. The first major prestressed structure in the United States was a bridge completed in Philadelphia, Pa., in 1951, and by the end of the 1950s prestressing had become an established part of the U.S. construction industry.

**Concrete Shells.**—Concrete shells are thin slabs of concrete shaped as a curved surface, the thickness being small compared to the lateral dimensions of the surface. The tremendous carrying capacity imparted by curvature is demonstrated by a table-tennis ball, which has exceptional strength and resiliency compared with the thinness of its plastic shell. Indeed, a plane sheet of plastic of the same thickness as the ball's wall is almost as flexible as a sheet of paper.

According to the shape of their surface, shells are classified as elliptically, parabolically, or hyperbolically curved shells, and as folded plates. Elliptical curvature (*e.g.*, the sphere) involves maximum rigidity and usually requires less material than other types. Built in reinforced concrete, however, elliptical shells require rather complex formwork. Parabolically curved shells are most frequently used, primarily because they are curved in only one direction so that the formwork can be made from straight boards or plane sheets. The simplest type is the cylinder, which is well suited for roofing rectangular areas. Hyperbolically curved shells are practically always shaped as a warped or saddlelike surface. Straight lines contained in the warped surfaces can often be utilized to simplify construction of the formwork. Folded plates consist of a series of flat plates inclined toward each other in accordion fashion. Beyond these four basic types, more complex forms have been used to achieve added architectural grace and beauty; *e.g.*, the shape of a seashell.

The basic principle of shell action is that every portion of a shell where a load may be placed is supported by compressive and tensile forces in the plane of the surrounding shell. A load applied to a plane slab, on the other hand, is resisted only by bending forces, with the consequence that the induced stresses are proportionately much more intense. A plane reinforced concrete slab three inches thick can be used to span only some 20 ft. when used as a roof cover. Shells with a thickness of three inches have been used to span several hundred feet.

Application of the shell principle in reinforced concrete construction was initially developed in Germany in the 1920s under the leadership of Franz Dischinger and Ulrich Finsterwalder. Since then, design theory and construction methods have been extended and improved greatly. The practicality and economy of shell roofs have led to their ever-increasing use throughout the world in gymnasiums, hangars, auditoriums, exposition halls, and many other industrial and commercial buildings that require high ceilings and large unobstructed floor areas.

**Architectural Concrete.**—Reinforced concrete can be used for both the ornamentation and the load-carrying parts of a building, so that aesthetic values are combined with structural practicality. For several decades, concrete was used almost exclusively

for load-carrying purposes, while its potential beauty remained unrecognized and undeveloped. Its emergence as an architectural material coincided with the development of the modern style of architecture characterized by clean, uncluttered lines.

An important property of architectural concrete is its plasticity when first placed, a quality that permits molding into practically any shape or form the architect may require. Thus, it allows almost complete freedom in architectural and functional design without sacrificing strength and economy. Concrete's plasticity is particularly valuable in construction of ornamental detail. All elements of a concrete building—ornamental as well as strength producing—may be cast integrally in a single operation at a substantial cost saving. Fluting, rustications, relief patterns, and other ornamental devices are executed easily and economically in concrete. Molds may often be reused many times to carry out a motif. A variety of paints, stains, coloured aggregates, and pigments used in the cement paste are available to increase the aesthetic value of architectural concrete.

**Fire Protection.**—Concrete is widely used as a casing around structural steelwork for protection against fire. Because of its high heat conductivity, bare steelwork soon reaches a dangerous temperature in a fire with consequent failure from softening. Concrete is a poor conductor of heat and furnishes protection by delaying the flow of heat to the encased steelwork. A thickness of two inches of concrete well bound to the steelwork by wire mesh reinforcement meets the protection requirements of many building codes and fire associations. A combination of structural steel and reinforced concrete is also used in which structural steel members, designed to carry a principal part of the load, are encased in reinforced concrete of such quality that the concrete also carries part of the load. The concrete then serves the dual purpose of strengthening and fire protection.

**Foundations.**—The foundations, those parts of a structure that serve exclusively to transmit the weight of the structure to the natural ground, are usually made of reinforced concrete. If a stratum of soil suitable for supporting a structure is located at a shallow depth, a single slab known as a mat or raft may be used to cover the supporting soil stratum beneath the entire area of the superstructure. Various parts of the structure may also be supported individually; a continuous footing supports a wall, a combined footing supports a group of columns, and an individual footing supports a single column. If the upper soil strata are too weak, the superstructure's loads are transferred to more suitable supporting soils or rock at greater depth by means of piles and piers. Concrete piles may be precast and driven into the soil, or they are cast in their final position in holes drilled into the soil.

### CONCRETE PRODUCTS

A variety of concrete products are produced in permanent factories. Specifications for the manufacture and performance of these products are issued by standards associations in most countries, and production is characterized by a high degree of mechanization and standardization.

**Concrete Masonry.**—Block and brick building units molded of concrete are often used for the construction of walls and other structural members. There are three principal steps in the manufacture of concrete masonry units: the careful proportioning and mixing of portland cement, water, and aggregates; molding of the units; and curing and drying. The units are molded by: tamping, in which the concrete is mixed to a semiwet consistency and then tamped into the molds; vibrating, in which a fairly stiff mix is consolidated in the molds by powerful vibration; or pressure, in which the concrete is placed in the molds and compacted by pressure. The units are removed from the molds on pallets immediately after compacting and placed in a curing kiln where the temperature is kept from 110° to 165° F (about 43° to 74° C). Heat and moisture speed up the hardening process. In some factories high-pressure steam curing in autoclaves is used.

Concrete masonry units are made in several sizes and shapes to fit different construction needs. The units are usually designated by their nominal dimensions. Thus, a unit measuring 7½ in. wide, 7½ in. high, and 15½ in. long is known as an 8 × 8 × 16-in.

unit. When it is laid in a wall with ¾-in. mortar joints, this unit will occupy a space exactly 16 in. long and 8 in. high. This is in accord with modular co-ordination of architectural design based on a four-inch module. In addition, there is a wide variety of nonmodular-size units. Either normal weight or lightweight aggregates are used. Normal weight units are made with sand, gravel, crushed stone, and air-cooled slag. Lightweight units are made with coal cinders, expanded shale, clay, or slag, and natural lightweight materials such as volcanic cinders, pumice, and scoria. Both hollow and solid units are made.

Units are produced to comply with the requirements of standards associations and local building codes. Compressive strength requirements provide a measure of concrete masonry's capacity to carry loads and withstand structural stresses with an adequate margin of safety. Absorption requirements provide a measure of the density of the concrete. Moisture content requirements are intended to indicate whether the unit is sufficiently dry for use in wall construction. In common with a number of building materials, concrete block shrinks slightly when moisture is lost. When moist units are placed in a wall and this natural shrinkage is restrained, as it often is, tensile and shearing stresses are developed which may cause cracks in the walls. Hence, it is important that the units be dried, and they must be kept dry during storage on the construction site.

Particularly in western Europe, patented methods of aerating concrete for masonry units are in use. Finely divided chemicals that generate gases are added to a mixture of portland cement and very fine silica sand, causing this paste to expand so that numerous small air spaces remain after hardening. Concrete units as light as cork are made in this manner; they can be sawed and drilled by carpentry tools. Aerated concretes are also made by mixing a preformed foam and a paste of cement, sand, and water. Most aerated concrete units must be high-pressure steam cured to control drying shrinkage.

Concrete units are used for all types of masonry construction, including load-bearing and non-load-bearing walls; piers; partitions; fire walls; backup walls for brick, stone, and stucco facing materials; fireproofing around steel columns, stairwells, and enclosures; and chimneys. Many plants also make concrete masonry sills, lintels, and concrete floor filler units.

**Concrete Pipe.**—This product is manufactured throughout the world for irrigation, drainage, sewers, culverts, and water supply mains. Pipe is made of either plain or reinforced concrete, and it can be produced to exhibit characteristics corresponding to the intended function.

Concrete pipe is made by several manufacturing methods. Cast pipe is made by placing concrete into forms of the desired sizes. In the "Packerhead" method, a very dry concrete mixture is packed into the form with such force that the freshly made pipe section can be taken to a curing shed where the form is removed immediately and the newly compacted pipe stands vertically during the curing and hardening period. Similar results are obtained by various other mechanical tamping methods. Centrifugal concrete pipe is manufactured in forms rotating at high speed so that the concrete is compacted as excess water is forced out by the centrifugal force. The pipe may be plain concrete, or it may be reinforced or prestressed concrete. Curing is accomplished by steam, water spray, saturated covers, or in water.

Pipe is produced to comply with the requirements of standards associations. Structural tests indicate the ability of the pipe to resist the pressure of soils in which it is buried. Freezing and thawing tests indicate resistance to ice pressures. Hydrostatic pressure tests reflect resistance to internal pressure.

**Cast Stone.**—Artificial building stone and even artistic sculpture are manufactured from concrete by a highly developed art that often makes use of intricate designs and patterns. By making forms of the desired shape and using coloured aggregates, colour pigments in the cement paste, and various grinding and polishing methods, a wide variety of architectural effects can be obtained. Forms for cast stone are constructed of metal, gelatin, plaster of Paris, concrete, plastics, wood, or sand, whichever is most convenient for the work involved.

**Precast Structural Concrete.**—Large structural members are made in a mechanized central plant and erected in buildings and bridges by cranes. A partial list of precast members would include piles and decks for bridges, floor and roof slabs, wall panels, joists, beams, girders, rigid frames, and shell units. Members from a few pounds to over 200 tons have been precast.

Precasting can be done by relatively crude methods at the building site; a mechanized temporary factory can be established at the site of extensive construction; and there are permanent factories in many countries. Several European factories are outstanding examples of highly mechanized mass production offering permanent employment for over 1,000 men. In the United States, precasting has been combined with prestressing techniques; a group of rapidly growing factories started production in the 1950s.

It is evident that economies may be realized from casting a bridge in a yard on the river bank rather than in midstream—and casting a building's beams in a factory rather than several stories up in the air. The most important aspect of precasting, however, is that it permits strict production controls which in turn make safe and economical use of unusually high quality concretes and highly advanced design techniques. Furthermore, precasting in factory buildings is protected from the weather—heavy rains and cold winter weather do not interrupt production. Complete buildings—even large industrial structures—have been factory precast in the winter and erected in a few weeks in the spring. This may provide important economies by advancing the date when a new structure begins to give economic returns.

More precast concrete factories have initiated a trend toward standardization of the cross sections of the precast beams and piles to facilitate economic and repeated use of forms. Some factories offer a variety of standardized sections made in whatever lengths are needed. Such products are often offered for sale in catalogues, including the strength and performance characteristics needed in architectural and engineering design of buildings and bridges assembled for each specific structure from precast units. Thus, individual members such as columns, beams, and slabs are standardized, but each building or bridge is custom designed to fit its particular function and architectural style.

### APPLICATIONS

**Bridges.**—There are four major types of concrete bridges: rigid frame, slab, girder, and arch (*see BRIDGES*). Any of these may consist of a single span or a series of several spans, the latter being referred to as multispans. By far the most widely used type of concrete bridge is the girder type, the economical span of which was greatly increased by the introduction of prestressed concrete. Numerous single-span prestressed bridges were built across European rivers following World War II. In the United States, a notable multispans bridge was built across Lake Pontchartrain near New Orleans, La., in 1956. Its total length of 24 mi. established a new world's record for concrete bridges. Most spectacular, however, are the long-span arch bridges. A notable example of the latter is Sweden's Sandö Bridge with its 866-ft. single free span across a turbulent river. This bridge, carrying a 34-ft. roadway, set a new record for reinforced concrete span length when it was completed in 1943. But this record was broken in 1964 by the unique Gladsville Bridge in Australia, which has a 1,000-ft.-long concrete arch.

The limited access highways brought about by modern traffic call for bridge construction on a scale without parallel in history. For example, the 41,000-mi. system of interstate highways begun in the United States in 1952 requires an estimated 27,000 bridges ranging from great river crossings to small bridges carrying secondary roads over the superhighways. Concrete bridge construction, which traditionally has concerned design and construction of a single bridge at a time, has therefore developed mass-production procedures. Thousands of concrete bridge girders weighing up to 50 tons each are produced annually in permanent factories for shipment and erection at bridge sites throughout western Europe, Britain, and the United States.

**Highways.**—The first concrete highways were built in Inverness, Scot., in 1865, and in Edinburgh in 1866. The first concrete

pavement in the United States was built in Ohio in 1892. Concrete highway construction on an enlarging scale began about 1910, and by the mid-1960s there had been constructed almost 3,000,000,000 sq.yd. of concrete highways and streets in the U.S.

**Design Requirements.**—The principal requirements in concrete highway design are strength and durability. Early pavement slabs were cast on the natural soils of the prepared roadbed. This practice is often inadequate for modern traffic. Some soils are affected by frost action; some swell when they come in contact with water; and some are susceptible to softening in the presence of excess moisture. For satisfactory performance of a concrete pavement on these soils, a four- to six-inch layer of granular material—sand, gravel, or crushed rock—may be required under the pavement to provide a well-drained foundation free from frost action. Considering the nature of the soil support, the concrete pavement is designed to resist the loads of moving vehicles by theories of slab strength originated by the Danish-American engineer H. M. Westergaard in 1926. To ensure durability of the pavement itself in the presence of severe frost action, the use of air-entrained concrete is essential; it became widely used in cold climates shortly after its development in the late 1930s.

To accommodate small changes in length of concrete pavement slabs caused by shrinkage or wide temperature change, longitudinal and transverse joints are used. For unreinforced pavements, the spacing of transverse joints is usually 15 to 30 ft., depending largely on the type of coarse aggregate used. Such joints are made by inserting a preformed strip or ribbon in the freshly placed concrete or by sawing narrow grooves in the hardened concrete.

In addition to strength and durability, the safety and comfort requirements of the traveling public call for additional major design considerations: First, the pavement must be smooth and have properly banked curves. By highly automated modern mechanical equipment, concrete pavements are trimmed to a precise tolerance of about  $\frac{1}{8}$  in., and smooth transitions between super-elevations of curves are carefully designed to facilitate driving. A gritty pavement surface that provides uniform traction and prevents skidding even when the pavement is wet, and good visibility at night are the two final design considerations. Several finishing methods have been developed to produce a granular, gritty surface; dragging a coarse broom transversely across the pavement is most commonly used. Broomed pavements are highly skid resistant and provide increased visibility at night because light from automobile headlights strikes the small transverse ridges and is reflected back to the driver. (*See also ROADS AND HIGHWAYS.*)

**Soil-Cement.**—Soil-cement is a tightly compacted mixture of soil or roadway material, portland cement, and water that forms a strong, durable pavement base as the cement hardens the soil. Developed in the United States in the early 1930s, soil-cement is generally built from soil on or near the paving site. Old, deteriorated granular materials can also be used. Only cement and water need be transported to the site.

The basic steps in soil-cement construction are spreading cement, mixing, and compacting. After the roadway has been shaped to grade and the soil loosened, the required amount of cement is spread. Cement and the required amount of water are thoroughly mixed with the soil by traveling mixing machines; the mixed material is then compacted by rollers, shaped to the proper pavement contour, and rolled again to obtain a smooth finish. A bituminous material is sprayed on the soil-cement soon after finishing to seal in moisture needed for the cement to harden the natural soil into a strong, low-cost pavement. The pavement is then completed by the addition of a concrete pavement or a bituminous surface.

In the mid-1960s about 36,000,000 mi. of soil-cement roads and streets were in service in the U.S., and airports had more than 35,000,000 sq.yd. of soil-cement runways.

**Airport Pavements.**—The first concrete airport pavement in the United States was built at the Ford Airport, Dearborn, Mich., in 1927. Thirty-five years later, 366,000,000 sq.yd. of concrete runways, taxiways, and aprons were in service at civil and military

airports in the U.S. The John F. Kennedy International Airport in New York, one of the world's largest and most modern airports, has seven concrete runways totaling ten miles in length. Each runway is 200 ft. wide by 12 in. thick and is constructed to accommodate aircraft weights up to 300,000 lb.

The design and construction methods for airport pavements are similar in nature to those used for highways, but weights of aircraft of more than 500,000 lb. are encountered, which far exceed the heaviest trucks in use. Similarly, skid resistance, overall pavement smoothness, and visibility at night are even more important than for highways. In addition to increased plane weights and speeds, the development of heavy jet aircraft has resulted in further design considerations. When these planes are moving slowly or standing still with engines "revving up" prior to takeoff, the pavement must withstand tremendous heat and blast. It is imperative that the pavement must not soften or disintegrate. Particles must not tear loose, since they would tend to enter air-intakes of other aircraft engines, damaging their rapidly moving turbines. Concrete has an inherent resistance to heat and blast. Adequate strength, durability, skid resistance, smoothness, and visibility can be provided economically. (See AIRPORT.)

**Railways.**—Among the essential structures of any railroad are its track, depots, freight houses, bridges, signal structures, and motive power maintenance and fueling facilities. In all of these concrete plays an important part. Cement grout—a mixture of portland cement, sand, and water—is forced into the ground underneath the track to stabilize troublesome pockets of water and soft soil, thereby providing an evenly supported railbed. Prestressed concrete ties (called "sleepers" in Britain) are used extensively in Europe. Most tunnels are lined with reinforced concrete to eliminate the hazards of falling rock, and reinforced concrete retaining walls are used extensively to prevent earth slides from disturbing the track.

**Harbour Facilities.**—In the shipping industry, concrete is widely used in the construction of harbour facilities (see HARBOURS), breakwaters, piers, warehouses, docks, canals, locks, dry docks, and even in ships. In some climates, the seas rising and falling with tides are above freezing temperature throughout the year, while the winter air may be considerably below freezing. In the tidal zone, therefore, concrete structures are subjected to severe repeated freezing and thawing and must be protected against frost damage by air entrainment.

In the construction of harbours and breakwaters, extensive use is made of huge precast concrete blocks made in a construction yard ashore. Some blocks are transported by barges and lowered into position by heavy cranes; others are made in the form of large boxes, referred to as caissons, that are launched, towed into position by tugboats, and sunk into position by opening valves in the bottom. Under the code name "Phoenix," such floating concrete caissons towed from England served a vital function in the "Mulberry" harbours during the 1944 invasion of Normandy. Extensive use was made of prestressed concrete structures in the reconstruction of west European harbour facilities after World War II, notably at Le Havre in France.

**Concrete in Small Buildings.**—Though they lack the spectacular features of heavy construction, the many small uses in housing and on farms make up a large volume of concrete—in some countries this is the largest single area of concrete usage. The foundations of most homes and farm structures are concrete. There are various types of concrete buildings used, and concrete enters into sidewalks, driveways, play courts, fireplaces, lily ponds, garden walls and benches, birdbaths, flagstone walks, swimming pools, and a variety of farm structures.

**Foundations.**—Strength, durability, and watertightness have made concrete ideal and widely used for construction of footings, which prolong the life of houses and farm structures by assuring uniform support on the soil. Footings for foundation walls should be built on firm soil below the lowest possible level of frost penetration, and they should be well drained. A basement constructed of ten-inch-thick concrete walls, footings, and a concrete floor can be a useful and attractive part of a home. To avoid cracking and

leaks, it is essential that a good quality concrete without excessive mixing water be used. In sections of the world where basements are not used, slab-on-ground concrete floor construction is becoming increasingly popular. A major reason is that concrete offers complete protection against rot and termites—an important consideration in warm climates.

**Masonry Homes.**—A common method of home construction is with block units made in factories, delivered to the building site, and laid into walls by masons. Concrete masonry house walls are usually built with eight-inch-thick units, although sometimes two walls are built of four-inch units with an air space between. Such walls lend themselves to almost any type of insulation.

A variety of attractive wall treatments may be produced in concrete masonry. Surfaces may be painted in any desired colour with portland cement paint or other suitable paints, or they may be left unpainted. Paint serves not only as a decorative finish but also as weatherproofing on exterior walls. Stucco may be applied to achieve whatever special surface texture will best suit the architectural style of the house. Units of different sizes may be laid together in a wall to form patterns traditional in stone work—for example random or coursed ashlar. Unusual effects may also be created with various block patterns and special treatments of mortar joints.

Concrete masonry is widely used as backup inside brick and stone facings to provide added strength and improved insulation. Particularly in the Scandinavian countries, very light block units made from special foam concretes are placed as insulation on the outside of houses and other buildings and covered with a weather-resisting layer of stucco.

**Reinforced Concrete Homes.**—These homes are produced by a variety of construction methods. Three types of walls are most frequently used when the concrete is placed in walls located in their final position. One type is a solid wall, four to eight inches thick according to strength and other requirements, with lath and plaster or other insulation applied to the interior surface. A second type, known as a cavity wall, consists of two four-inch walls with a two-inch air space between them. In a third type, a high-air-content concrete is used to provide adequate thermal insulation without a cavity. The exterior concrete surface can be given a wide variety of textures and colours.

Tilt-up construction is a fast, economical method in which walls are cast on a horizontal base and then tilted and lifted into position by cranes after the concrete has hardened. It is economical because it requires a minimum use of forms and permits efficient use of modern mechanical equipment. The fact that the exterior wall surface may be finished in a horizontal position facilitates inexpensive preparation of a variety of architectural effects. The top surface of such walls is often covered by a thin layer of coloured aggregate concrete. The cement paste is removed by brushing soon after it has begun to harden so that the coloured aggregate is exposed to form an attractive exterior finish when the wall panels later are tilted and lifted into position.

Various methods of constructing reinforced concrete houses developed in the late 1940s involve extensive use of large sections manufactured in heavily mechanized factories and erected at the site. This method is particularly well developed in Denmark, the Netherlands, and the U.S.S.R.

**Farm Structures.**—Dairy barns, feeding floors, farrowing houses for hogs, poultry houses, silos, and other structures are often constructed of concrete to reduce fire losses by eliminating combustible construction materials, to curb livestock diseases by improving sanitation, and to obtain durable, warm, dry structures. Both masonry block units and reinforced concrete are used in wall construction. Concrete-paved yards and feeding floors are generally four inches thick, and a stiff broom is stroked against the surface of the fresh concrete to provide a nonslip surface.

Concrete stave silos are constructed of hundreds of interfitting units about 10 in. wide, 30 in. long, and 2½ in. thick. As the factory-made staves are being fitted to form the silo wall, external steel reinforcing rods are tightened to hold firmly against internal pressure—like the hoops of a barrel. Silo walls are also cast at the farm site by placing concrete in circular forms, which are

raised as construction progresses. The walls are usually 6 in. thick and are reinforced. Large reinforced concrete grain elevator structures are constructed in rural areas. Concrete is also used in structures preventing soil erosion.

**Dams.**—Gravity, arch, and buttress dams are the three major types of concrete dams. Gravity dams are essentially triangular in cross section. The upstream face is steeply inclined, while the downstream face slopes gradually to provide a width at the dam base equal to 0.65 to 0.85 times the dam height. The heavy gravitational weight of these dams prevents them from sliding on their foundation base and from overturning under water pressure. The large mass of gravity dams leads to several complications in concreting operations. For example, the heat developed when portland cement reacts with water is not a problem for thin sections, but this heat of hydration must be safely dissipated in large dams by elaborate systems of cooling pipes. Crushed ice added to the concrete mixture as part of the mixing water and fanning of aggregate stockpiles are also used to control the development of heat. Arch dams consist of a single horizontal arch; they are suitable only for narrow gorges with sound rock at the sides to absorb the thrust from abutments. Water pressure is resisted partly by arch action, partly by cantilever action since the dam is in contact with the bottom of the gorge, and partly by the weight of the dam. This combined action leads to complex design methods, in the solution of which electronic computers and model tests are most helpful. Buttress dams consist of a series of triangular-shaped buttresses which support a series of concrete slabs or arches resisting the water pressure. (See DAM.)

**Irrigation.**—The extensive use of concrete in modern irrigation stems from the fact that it is important to store, transport, and use the available water without undue loss through evaporation and seepage. Concrete lining of canals effectively prevents seepage losses, which average about 40% of the water transported in unlined canals. Underground concrete pipelines are also used extensively to transport water. Since pipe systems can operate under pressure, water can be delivered to land that could not be served by canals. Concrete is used to line tunnels and to construct siphons and flumes for carrying water over, under, and through natural and man-made barriers such as rivers, mountains, valleys, highways, and railroads. (See also IRRIGATION.)

**Water Supply.**—As water consumption increases, it has become necessary for many cities to transport water from distant natural sources. Others have impounded water in artificial reservoirs. To provide the source of water supply, concrete is used in the construction of dams, spillways, intakes, and pump houses. Most storage reservoirs are constructed of concrete to form an impervious barrier preventing water loss by seepage, to facilitate cleaning of the reservoir, and to protect the stored water from contamination. Finally, high-pressure concrete pipe is used extensively in the water distribution system as main lines 12 in. or more in diameter (see WATER SUPPLY AND PURIFICATION).

**Sewage Works.**—These installations are required to control disease and prevent pollution of rivers and lakes. Concrete has been used in sewer construction since Roman times. In modern practice, concrete sewer pipe is used in sizes from 6 in. to 12 ft. in diameter. Concrete is used for large sewer tunnels which are often cast in their final position using traveling forms.

**CONCRETION**, in petrology, a name applied to nodular or irregularly shaped masses of various size occurring in a great variety of sedimentary rocks, differing in composition from the

main mass of the rock, and in most cases obviously formed by some process which ensued after the rock was deposited. As these bodies present so many variations in composition and structure, it will conduce to clearness if some of the commonest be briefly described. In sandstones there are often hard rounded lumps, which separate out when the rock is broken or weathered. They are mostly siliceous, but sometimes calcareous, and may differ very little in general appearance from the bulk of the sandstone. Through them the bedding passes uninterrupted, thus showing that they are not pebbles; often in their centres shells or fragments of plants are found. Argillaceous sandstones and flagstones very frequently contain "clay galls" or concretionary lumps richer in clay than the remainder of the rock. Nodules of pyrite and marcasite are common in many clays, sandstones and marls. Their outer surfaces are tuberculate; internally they commonly have a radiate fibrous structure. Usually they are covered with a dark-brown crust of limonite produced by weathering; occasionally imperfect crystalline faces may bound them. Frequently these pyritous nodules contain altered fossils.

Another type of concretion, abundant in many clays and shales, is the "septarian nodule." These are usually flattened, disk-shaped or ovoid, often lobulate externally like the surface of a kidney. When split open they prove to be traversed by a network of cracks, which are usually filled with calcite and other minerals. These white infillings of the fissures resemble partitions; hence the name from the Latin *septum*, a partition. Sometimes the cracks are partly empty. They vary up to one-half inch in breadth, and are best seen when the nodule is cut through with a saw. These concretions may be calcareous or may consist of carbonate of iron. The former are common in some beds of the London Clay, and were formerly used for making cement. The clay-ironstone nodules or sphaerosiderites are very abundant in some Carboniferous shales, and have served as iron ores; some of the largest are three feet in diameter, and in the centre fossils are often found, e.g., coprolites, pieces of plants, fish teeth and scales. Phosphatic concretions are often present in certain limestones, clays, shelly sands, and marls.

Another very important series of concretionary structures are the flint nodules which occur in chalk, and the patches and bands of chert which are found in limestones. Flints consist of dark-coloured cryptocrystalline silica. They weather gray or white by the removal of their more soluble portions by percolating water. Their shapes are exceedingly varied, and often they are studded with tubercles and nodosities. They sometimes have internal cavities and frequently contain shells of echinoderms, mollusks, etc., partly or entirely replaced by silica, but preserving their original forms. Chert occurs in bands and tabular masses rather than in nodules; it often replaces considerable portions of a bed of limestone (as in the Carboniferous limestone). Corals and other fossils frequently occur in chert, and when sliced and microscopically examined both flint and chert often show silicified foraminifera, polyzoa, etc., and sponge spicules.

These examples will indicate the great variety of substances which may give rise to concretions, which seem to arise from the tendency of chemical compounds to be slowly dissolved by interstitial water, either while the deposit is unconsolidated or at a later period; it is highly probable that such solutions are usually in the colloidal state. Certain nuclei, present in the rock, then determine reprecipitation of these solutions, and the deposit once begun goes on until either the supply of material for growth is exhausted, or the physical character of the bed is changed by pressure and consolidation until it is no longer favourable to further accretion. The process resembles the growth of a crystal in a solution by slowly attracting to itself molecules of suitable nature from the surrounding medium; but in the majority of cases it is not the crystalline forces, or not these alone, which attract the particles. The structure of a flint, for example, shows that the material had so little tendency to crystallize that it remained permanently in cryptocrystalline or subcrystalline state. That the concretions grew in the solid sediment is proved by the manner in which lines of bedding pass through them and not around them.

(J. S. F.)

**CONCUBINAGE** is the state of cohabitation of a man and a woman as married persons without the full sanctions of legal marriage. The term is derived from the Latin *concubina*, a concubine (from *con*, "with" and *cubare*, "to lie"). Most societies recognize more than one kind of marital relationship, the legal status of the woman being a determinant of the legal status of her offspring. The children of a full marriage are legitimate and are thereby endowed with specific rights of inheritance and succession, but the children of a lesser-grade marriage, though "illegitimate" in some senses, may still possess definite legal rights. The story of Hagar (Gen. xxi, 10 ff.) and the account of Abraham's gifts to the sons of his concubines (Gen. xxv, 6) exemplify such a distinction.

In Roman law a state of fully legitimate marriage could be established either as the result of public ceremonies (*confarreatio* or *coemptio*) or less formally on the basis of *affectio maritalis* by declaring a fixed intention of taking a particular woman as a permanent spouse, as in Scottish law. The Romans were strictly monogamous and a man legally could not maintain more than one spouse, of whatever category, at any one time. The Roman *concubina* differed from a wife married in *affectio maritalis* in that (1) she brought her husband no dowry (*dos*); (2) she was not raised, like the wife, to the rank of her husband; and (3) her children were not legally the relatives of the father but cognates of the mother. In the 4th century A.D. Constantine the Great ruled that the marriage of a *concubina* should legitimate her children as heirs to her husband provided that there were no existing legitimate heirs; Justinian allowed this even if there were legitimate heirs. The *concubina* was usually of lower rank than her husband but the relationship did not entail stigma. On the contrary, some men of high rank took respectable concubines because they were discouraged by the immorality of higher ranking Roman women with whom they could have made orthodox marriages. That *concubina* continued to be recognized as a distinct but respectable status as late as the 11th century is evident from injunctions by church councils at Rome that a layman who had a wife and a *concubina* at the same time should be suspended from communion.

The institution of morganatic marriage (*q.v.*), which was widely current in diverse forms among the nobility of medieval Europe, was similar to Roman concubinage in many respects. A noble who married a commoner was deemed fully married in the eyes of the church, but the commoner wife did not assume the rank of her husband, and the children's rights (whether the wife or husband was of lower rank) to inheritance and succession in the property and titles of their parent of higher rank were severely circumscribed.

Christian legal theory is quite unambiguous—a man may have one wife only and her marriage must be explicitly established by church ritual—but civil practice has often been relatively flexible. For example, in the 17th century, although the only legitimate heirs of the English and French kings were the children of their properly married queens, the kings' numerous bastard offspring were regularly raised to the nobility. Moreover, the mothers of these children had an honourable public status which might fairly be described as one of concubinage.

The concubinage of later medieval Europe was likewise a reflection of the divergence between the rigid requirements of canon law and the less precise conventions of practical behaviour. In 1241 the Jutland code of Valdemar II provided that a concubine kept openly for three years should thereby become a legal wife; this section of the code remained in force till 1582. A similar custom (handfasting) prevailed in Scotland. In the 13th century, the English jurist Henry de Bracton wrote of *concubina legitima*, a status which seems to have differed from that of wife only as regards ceremonial and in being a less strong position from which to claim a widow's dower after her husband's death. A wife was married in church, a "legitimate concubine" was not.

It was the clergy themselves who benefited most from this distinction. In the 12th century the Roman Church declared that any marriage made after ordination was invalid, but those who were denied a wife often took a concubine instead. It is against this background that one must view the rejection of clerical celi-

bacy by Protestant reformers in the 16th century. It should be noted that the context of European concubinage is consistently monogamous. It is not the inferior standing of the concubine herself that is stressed but the inferior legitimacy of her offspring. In contrast, where the term concubine has been applied to non-European institutions the emphasis is on the inferior status of the woman, the context being that of polygyny. For example, Koranic law permits a man to have not more than four wives at any one time. Where a Muslim harem contains numerous women, the excess over the Koranic four are rated as concubines or slaves. In many cases there is no discrimination between the children of wives and the children of concubines, but a wife is entitled to receive a widow's dower from her husband whereas a concubine is not.

The marital customs of the Ottoman monarchs were in this respect extreme. By the 16th century the sultan very seldom took any legal wife, all his women having the status of slave-concubine. A concubine who bore a child was raised to the rank of *haseki* and the chief of these, the mother of the first male child, was second only to the sultan's mother within the harem. But in a technical legal sense even the highest *haseki* were slaves and not wives.

In traditional China the context of concubinage was rather similar. Confucian orthodoxy combined an ideal of lifelong marital union with the obligation that all males should produce male heirs. Divorce was impossible but it was considered morally proper for the husband of a barren wife to take a concubine to raise up progeny; in practice, most concubines were taken simply for sexual pleasure. The marital status of the Chinese concubine hardly differed from that of the legitimate wife and her children were legitimate, but, whereas the wife would belong by birth to the same social class as her husband, the concubine was more likely to have been reared as a slave or in a brothel.

It is important to remember that the word concubine was initially applied to non-European institutions by missionaries who had a prejudice in favour of Biblical terminology and the virtues of monogamy. Anthropology has shown that, in the world at large, polygamy is no less admired than monogamy and in polygynous households the statuses of the different women and of their respective offspring may be differentiated in a variety of complicated ways. The ordinary English meanings of the words wife, concubine and slave are often inappropriate to such situations. A phrase such as secondary or junior wife will usually be less misleading than the term concubine with its specific Biblical and Roman law associations.

**CONDÉ, PRINCES DE**, the heads of an important French branch of the house of Bourbon (*q.v.*). The property of Condé at Hainaut (Condé-sur-l'Escaut, in the modern French *département* of Nord) had passed, together with the countship of Enghien, into the possession of François de Bourbon, comte de Vendôme, through his marriage with Marie de Luxembourg in 1487.

**Special Designations.**—As the leading adult prince of the French royal blood on the Huguenot side (apart from the king of Navarre), Louis, 1st prince de Condé (*see below*), came to be designated colloquially by the Huguenots as *Monsieur le Prince*, without any further specification. This designation was soon generally adopted and passed to his successors. The 3rd, 4th and 5th princes, however, were also premier princes of the blood (*see below*) from 1589. Hence in the 17th century the designation came to be regarded not as a hereditary right of the Condés but as attached to the rank of premier prince. Thus when the Condé could no longer claim that rank, the designation ceased to be theirs (with the 5th prince's death). In the 4th prince's lifetime, meanwhile, his eldest son, as duc d'Enghien, had been able to assume the designation *Monsieur le Duc*, without further specification, and this was retained, after the 5th prince's death, by his son, the duc de Bourbon, who passed it also to his successor.

**The Huguenot Leaders.**—LOUIS I DE BOURBON (1530-69), 1st

prince de Condé, was born at Vendôme on May 7, 1530, the hunchback youngest son of Charles, duc de Vendôme, and Françoise d'Alençon. Brought up among Huguenots, he was married in 1551 to Éléonore de Roye, a Huguenot herself. He served in Henry II's armies in the campaigns of 1551–57, but won no favour. On Henry II's death (1559), Condé came forward as the military leader of the Huguenots: he needed their backing to make himself at all considerable politically; they needed a princely patron more resolute than his eldest brother Antoine, king of Navarre, though Condé's licentious way of life accorded ill with their principles. On the failure of the Huguenot conspiracy of Amboise (March 1560), Condé fled from court. On presenting himself to Francis II at Orléans (Oct. 1560), he was arrested and, on Nov. 26, sentenced to death. The king's death (Dec. 5) saved him, as the new regent, Catherine de Médicis, needed him to counterbalance the Guises, with whom he was formally reconciled in Aug. 1561. After the massacre of the Huguenots at Vassy (March 1562), he occupied Orléans and marched on Paris, but was defeated and captured by François de Guise at Dreux (Dec. 19). For the three years following the peace of Amboise (March 1563) he tried to restrain the Huguenots and collaborated with the government, being preoccupied with love affairs. His first wife died in 1564, and he married Mlle de Longueville (Françoise d'Orléans) in 1565. Finally, however, disappointed in his hope of being made lieutenant general of the kingdom and alarmed at the government's dealings with Spain, he left the court again (July 1567) and led the Huguenots in another attack on Paris. Defeated in battle at St. Denis (Nov. 10), he made a skilful withdrawal and then, reinforced by German mercenaries, went to besiege Chartres (Feb. 1568). He signed the peace of Longjumeau (March 1568) against the admiral de Coligny's advice. When war broke out again in August, he found himself tied down to operations in western France. Fighting to save Coligny at Jarnac (March 13, 1569), he had to give himself up to the enemy and was shot through the head on the spot. He left three sons by his first wife, Henry (*see below*), François, prince de Conti (1558–1614), and Charles (1562–94), cardinal de Vendôme; and one by his second, Charles, comte de Soissons (1566–1612).

HENRY I DE BOURBON (1552–88), 2nd prince de Condé, was born at La Ferté-sous-Jouarre on Dec. 29, 1552. His father's death left him and his cousin Henry of Navarre as titular leaders of the Huguenots. After the peace of St. Germain (1570) Condé retired to Béarn and married Marie de Clèves. She died after giving birth to his daughter Catherine (1574–93). Condé, meanwhile, caught in Paris during the massacre of St. Bartholomew's day (1572), had been forced to confess Catholicism. Nominally governor of Picardy, he was kept under surveillance till, in 1574, he escaped to Alsace and began raising troops for the Huguenots. Invading France with a horde of mercenaries to collaborate with the duc d'Alençon, he was disappointed at the terms which Alençon made with the government (1576). In the next civil wars (*see FRANCE: History*) he became rather an embarrassment to Henry of Navarre, set himself up as chief of the most fanatical Huguenots and failed conspicuously in his travels abroad in search of foreign help (1580) and in his campaign of 1585 in western France—when he was driven to take refuge in Guernsey. Returning to France, he married, in 1586, Charlotte de La Trémoille (1565–1629), who renounced Catholicism for him and bore him a daughter, Éléonore (1587–1619). Wounded at the battle of Coutras (Oct. 1587), Condé died suddenly at St. Jean-d'Angély on March 5, 1588.

**The Premier Princes of the Blood.**—The princesse de Condé (La Trémoille) was accused of having poisoned her husband, and doubts were cast on the paternity of the son to whom she gave birth on Sept. 1, 1588. HENRY II DE BOURBON, 3rd prince de Condé (1588–1646). Henry IV of France, however, rejected these allegations and recognized his cousin as his heir presumptive until the birth of the dauphin, later Louis XIII. Henry IV's accession to the crown, moreover, meant that Condé became premier prince of the blood (*premier prince du sang*), a rank that was conventionally regarded as still his even after the birth of Henry IV's younger sons, as they had the superior quality of *filz de France* (sons of an actual king). Moreover, as the new quality of *petitfils de France* (grandson of a sovereign, viz. of Louis XIII) was to be accorded

to Louis XIV's nephew, the future regent Philippe duc d'Orléans, the rank of premier prince, in this conventional sense, was allowed to the Condés for three generations in all.

The 3rd prince de Condé was brought up as a Catholic by his mother, who abjured Calvinism in 1596. In 1609 he married Charlotte de Montmorency (1594–1650). The new princesse, however, attracted Henry IV so much that Condé had to send her out of the country and then to flee abroad himself to escape the king's fury. After Henry IV's assassination he returned to France (July 1610), to compete with the other princes and nobles in making demands on the regent, Marie de Médicis. When she and the marquis d'Ancre (*q.v.*) began to refuse his demands, he twice blackmailed them by open rebellion, obtaining not only money but the governments of important strongholds under the treaties of Ste. Mennebold (May 1614) and Loudun (May 1616). Finally he was arrested (Sept. 1616).

Three years of prison (till Oct. 1619) changed Condé's mind. Thenceforth he was the crown's obsequious servant, operating against the rebellious princes in 1620; against the Huguenots—whom, in reaction from his ancestral tradition, he particularly detested—in 1621 and in 1627–29; and in frontier campaigns till 1638, when his invasion of Spain ended in disaster at Fuenterrabia. Rewards included the government of Burgundy (1631), which remained a family perquisite, and most of the property confiscated from his brother-in-law Henry de Montmorency (executed in 1632). Part of this was Chantilly, which became the Condés' principal country seat. Under Anne of Austria's regency he supported Cardinal Mazarin. He died in Paris on Dec. 26, 1646. His children were Anne Geneviève, duchesse de Longueville (*q.v.*); the Great Condé; and Armand, prince de Conti (*see CONTI, PRINCES DE*).

For the 4th prince, the Great Condé, *see* CONDÉ, LOUIS II DE BOURBON, PRINCE DE.

HENRY JULES DE BOURBON (1643–1709), 5th prince de Condé, was born in Paris on July 29, 1643, the eldest son of the Great Condé. Known from 1646 as the duc d'Enghien, he was taken to and fro by his mother during the Fronde and eventually into exile with his father, returning to France in 1659. He was married in 1663 to Anne of Bavaria, daughter of Edward, prince Palatine. At this time he was proposed as a candidate for the Polish throne. His father tried to embark him on a military career, but Henry Jules showed no aptitude, though he served in campaign after campaign between 1666 and 1693. On his father's death (1686), however, he devoted himself chiefly to expanding and improving Chantilly. A little man, interested in the arts, the sciences and technology, an able courtier and a magnificent host, he was eccentric, given to malicious practical jokes and a terror to his wife and children. In his last years he was mentally quite deranged. He died in Paris on April 1, 1709. Of his nine children by his wife, one son and three daughters survived him, the most notable being Anne Louise Bénédicte (1676–1753), duchesse du Maine.

**The Last Princes.**—LOUIS III DE BOURBON (1668–1710), 6th prince de Condé, born on Oct. 10, 1668, was the 5th prince's second son and eventual successor. Almost a dwarf, with an enormous head and a yellow complexion, he was notoriously malevolent and offensive. In 1685 he was married to one of Louis XIV's bastards, Louise Françoise de Bourbon (previously known as Mlle de Nantes). As a soldier (from 1688), he showed bravery, notably in the battles of Steinkerke (1692) and Neerwinden (1693). On his father's death he was unable to assume the designation Monsieur le Prince (*see above*) since the Condés could no longer claim the rank of premier prince. He therefore never used his title of prince de Condé, continuing to be known as Monsieur le Duc (he was duc de Bourbon). He died suddenly in Paris on May 4, 1710, leaving three sons and six daughters by his wife.

For the 7th prince, *see* BOURBON, LOUIS HENRI, DUC DE.

LOUIS JOSEPH DE BOURBON (1736–1818), 8th prince de Condé, was born in Paris on Aug. 9, 1736, only son of the duc de Bourbon and Charlotte of Hesse. He assumed the Condé title on his father's death (1740). In 1753 he married Godefride de Rohan-Soubise (d. 1760). Brought up for the army, he did good service in the Seven Years' War. On the fall of the Bastille (1789), he was one

of the first princes to emigrate. Establishing himself at Worms in 1791, he set about raising the *émigré* "army of Condé," which took part, not very effectively, in the antirevolutionary campaigns of 1792-96 (see FRENCH REVOLUTIONARY WARS). After the Franco-Austrian peace of 1797, Condé went to Russia, served with the Russians in 1799, then passed to Austria in 1800 and to England in 1801. Returning to France in 1814, he died in Paris on May 3, 1818.

LOUIS HENRI JOSEPH (1756-1830), 9th prince de Condé, born in Paris on April 13, 1756, the 8th prince's son. As duc de Bourbon, he was married in 1770 to Louise Marie Thérèse d'Orléans (1750-1822), who bore him a son, Louis Antoine, duc d'Enghien (q.v.), in 1772, but from whom he parted in 1780. Emigrating with his father and son in 1789, he went in 1795 to England to prepare the abortive expedition of the comte d'Artois (see CHARLES X, king of France) to the Vendée. Thereafter he gave himself up to sordid ease in London, where he picked up Sophie Dawes, the future baronne de Feuchères (q.v.). Returning to France in 1814, he tried to organize resistance in Anjou during the Hundred Days, then escaped to Spain till the Second Restoration. On his father's death he did not assume the Condé title. As Enghien had been shot at Napoleon's behest in 1804, the duc de Bourbon had no heirs, so that in 1829, to ingratiate herself with the house of Orléans, his mistress made him leave the residue of the Condé inheritance (after splendid bequests to herself) to Henri d'Orléans, duc d'Aumale. On Aug. 27, 1830, he was found hanging from a window fastening in his bedroom at St. Leu, the magnificent estate that he had bought six years earlier.

This ended the great house of Condé. Aumale in gratitude chose the title prince de Condé for his elder child, Louis (1845-66), and wrote a monumental study of the first four princes, *Histoire des princes de Condé* . . . , 7 vol. plus index and maps (1863-96).

(J. G. R.-S.)

**CONDÉ, LOUIS II DE BOURBON**, PRINCE DE (1621-1686), called THE GREAT OR LE GRAND CONDÉ, or MONSIEUR LE PRINCE LE HÉROS, French prince and general, was born in Paris on Sept. 8, 1621, son of Henry II de Condé and his wife Charlotte de Montmorency. The sense of being a prince of the royal blood of France (see CONDÉ, PRINCES DE) dominated Condé's life; even in his deathbed letter to the king he mentioned his birth. From this came his contempt for the lesser princes, his indecision in opposing royal authority in the person of the queen regent and, finally, his submission to the monarchical dogma of Louis XIV.

His father gave to the duc d'Enghien, as he was at first called, a complete and strict education: six years with the Jesuits at Bourges, as well as mathematics and horsemanship at the Royal Academy at Paris. At 17 he was governor of Burgundy, in touch with the armies of the Thirty Years' War (q.v.). Cardinal de Richelieu and Louis XIII, visiting him at Dijon, noted his fitness for a command. His father had long intended to marry him to the cardinal's niece, Claire Clémence de Maillé-Brézé; and after Enghien had served as a volunteer with the army in Artois, working hard as a professional soldier, they were married (Feb. 1641). She was barely 13, and they began so badly that the cardinal summoned him to Narbonne (1642). There, during the conspiracy of Cinq-Mars, the cardinal appreciated his loyalty, and before his death the king had agreed that the young Enghien should command an army in 1643.

Less than a month after Enghien had taken command at Amiens he heard that the Spaniards, far to the east, were attacking Rocroi and would invade Champagne; he also received news of Louis XIII's death, but from the first he acted with full professional confidence. He marched straight to the enemy, placed his army before them in battle order too rapidly for a countermove and next day (May 19, 1643) began the battle of Rocroi by breaking the opposing cavalry wing. He checked his horsemen and turned them on the rear of the Flemish infantry, moved on to rally his own defeated left wing and concentrated his troops to crush the strong core of old Spanish regiments. It was the greatest French victory for a century and due, beyond question, to his personal effort. He had the genius for direct, decided action on the military facts which faced him.

In 1644 Gaston, duc d'Orléans, as Louis XIV's uncle, claimed the main army command. Enghien collected troops in Champagne and was sent, not to Flanders to help Gaston but east to reinforce the marshal de Turenne. As prince he could give orders to the marshal, though Turenne was ten years older and had the larger army, but they were good colleagues. Their repeated attacks failed to break the lines of the Bavarian general Franz von Mercy near Freiburg, but at last Mercy withdrew. Enghien seized Philippsburg as a base across the Rhine and occupied the Rhineland up to Mainz, an occupation which his control of his troops made tolerable to the inhabitants. In July 1645 he came again to help Turenne on the borders of Bavaria, far into Germany. Their victory at Nördlingen (Aug. 3) after costly frontal attacks on strong positions, drove the Bavarians across the Danube and completed Enghien's fame as a great commander. During the campaign of 1646 he went to serve under the ineffective Gaston d'Orléans in Flanders; then gout brought Gaston back to court, and in two months Enghien had secured the great prize of Dunkerque.

His father died on Dec. 26, 1646, and Enghien became prince de Condé and premier prince of the blood. Now he had power as well as glory and so was carefully watched by Cardinal Mazarin (q.v.), chief minister of the queen regent, Anne of Austria. In 1647 he was sent to restore the defeated army in Catalonia and to strike some blow which would force Spain to accept peace on French terms. (If Masaniello's revolt in Naples and Henry de Guise's attempt to win that kingdom had been more successful, Condé might have been moved still farther from the centres of power in France.) He invested Lérida (with the legendary gesture of the fiddlers leading the first trench party). Paris, expecting Lérida's fall, was disappointed when Condé decided that he must be free to move against the growing Spanish army and raised the siege. He held Catalonia successfully, but Lérida was a blow to his reputation, as both he and Mazarin knew. Mazarin had to give Condé the Flanders command in 1648, but listened more to his subordinates than to him and split up the army for different objectives. Condé had only part of his army when he seized the opportunity for a battle at Lens (Aug. 20) and by his tactical mastery, a simulated retreat drawing the enemy out, crushed the Spanish forces under the archduke Leopold and secured the signing of peace at Münster.

With this victory power swung back to Condé on his return from Flanders, for Mazarin was faced by the first emergence of the Fronde (q.v.). Condé had his own personal grievances against Mazarin (a list of promotions and appointments not granted to his friends and family) and did not like Mazarin's sudden coup d'état, but he despised the house of Vendôme and the duc de Beaufort, its representative among the Frondeurs, and could not be courteous to the lawyers of the Paris *parlement*. In any case he alone could provide and command the troops for the blockade of Paris, which began in Jan. 1649. The peace of Rueil, in the following March, left him undecided. He was not a party leader; he could not agree with his brother Armand, prince de Conti, or with his sister Anne, duchesse de Longueville, or even with the duchesse de Châtillon (Isabelle Angélique de Montmorency-Boutteville), sister of one friend and widow of another, whom he much admired. Yet all the intriguers, Mazarin, Gondy (the future cardinal de Retz), the duchesses and the other princes were bound to consider him for an alternative government. Certainly he was not a conspirator, though every violent speech of his was exploited. Mazarin resolved the case by arresting Condé, Conti and their brother-in-law, the duc de Longueville (Henry d'Orléans) on Jan. 18, 1650, when they were in attendance at court. They were in prison for 13 months. Their supporters began civil war. (See FRONDE.)

When the queen regent had to yield in Paris, Mazarin, before leaving France, released his prisoners at Le Havre on Feb. 16, 1651. Condé was well received in Paris and for three months was almost in control of France. He gave posts to his lieutenants and governments to his friends, he secured the return of Turenne (who had rebelled on his behalf) to France, he even welcomed his wife, who had taken up arms for him at Bordeaux. But neither the

court nor Frondeurs accepted him and he was soon taking precautions for his own security. He was safe neither from arbitrary arrest by the queen regent's guard, nor from murder, so in July he moved outside Paris. In Sept. 1651 he was in armed rebellion, and in November he signed a formal treaty which his agents had negotiated with the Spaniards for common action against the French government as long as it remained under Mazarin's influence.

Mazarin's return to France (Dec. 1651) made Gaston d'Orléans and the Frondeurs in Paris ready to come to terms with Condé. After riding in disguise with only eight companions from Guienne to the Loire, Condé took command of the rebel princes' army that was awaiting him and fought the battle of Bléneau (April 6-7), in the latter stage of which he was opposed by Turenne, now on the side of the government. He entered Paris in triumph on April 11. Yet he made no new friends and secured control over nobody. Indecision, violent tempers and illness exhausted him. He was nearly captured by Turenne in the astonishing battle of the Faubourg St. Antoine (July 2, 1652), in the streets outside the wall of Paris, but was at the last moment let in through the gate. At last, in October, he left Paris with 3,000 men, without money or resources to maintain independent action in Champagne. In less than a year he was only one of the king of Spain's commanders in the Netherlands, and not even the chief one. As a soldier, however, his exploits in the Spanish service were still splendid: his retreat from Arras (1654); his victory at Valenciennes (1656); his relief of Cambrai (1657). Each of these exploits was so exact an appreciation of the facts as to be a stroke of genius. From the final battle of the Dunes before Dunkerque (June 14, 1658) he did little more than escape; he advised against battle and the ground was unfit for his cavalry.

After the treaty of the Pyrénées (1659) Condé returned to France in Jan. 1660. There followed illnesses, debts, disappointed lieutenants and his final separation from his wife, whom he and his son callously confined at Châteauroux in 1671 for the rest of her life, when she was probably mentally disordered. His seat at Chantilly, however, became a centre of the arts of peace, visited by the most brilliant men in Europe. He enjoyed the possibility of being elected king of Poland, but was completely submissive to the royal will, which for some years kept him from politics and war. In 1672 Louis XIV flattered himself with the great parade of the invasion of Holland (*see* DUTCH WARS) and with Turenne and Condé as his lieutenants, but in a skirmish near Arnhem (June 12) Condé was wounded and his nephew, the young Charles Paris de Longueville, killed. Afterward Condé was appointed to real commands, but with small forces, on the Moselle and then at Utrecht. In 1674 he commanded in the Netherlands, completed the evacuation of Holland and, from his well-chosen camp near Charleroi, faced the much larger allied armies. In the battle of Seneffe (Aug. 11) he cut off their rearguard of 8,000 men, but was engaged by William of Orange with increasing numbers from which he could escape only by continuing to attack. Both armies gladly withdrew in the night. Condé, wearing slippers and stockings because of his gout, had been in the saddle for 26 hours, and three horses were killed under him.

On July 31, 1675, Condé received the news that Turenne had been killed and the king's order to replace him in Alsace. He left the Netherlands at once, restored the confidence of the troops on the German front and maneuvered from one strong position to another until Raimund Montecuccoli abandoned Alsace and the Rhineland and took the imperial army back across the Rhine.

This was the end of Condé's active service; he was now so crippled that he could hardly move. He ceased to attend the king's council, but all the soldiers and statesmen came to Chantilly, and he enjoyed the king's full respect. The prince died at Fontainebleau on Dec. 11, 1686.

*See* Henri d'Orléans, duc d'Aumale, *Histoire des princes de Condé pendant le XVII<sup>e</sup> et XVIII<sup>e</sup> siècles*, vol. iii-vii (1886-96). (I. D. E.)

**CONDELL, HENRY** (d. 1627), English actor and friend of Shakespeare, may have been acting as early as 1590-91 but first appears definitely in 1598 in the cast of *Every Man in His Humour*. Thereafter, he was regularly with Shakespeare's company ("the

Lord Chamberlain's men," "the King's men"), retiring as a man of substance about 1623. His name and that of John Heminge (*q.v.*) were linked with Shakespeare's for 30 years: they had been associates financially and as fellow actors in the Blackfriars and the Globe theatre, and Shakespeare left each of them a token remembrance in his will.

Condell and Heminge seem to have been the chief movers in sponsoring and preparing the Shakespeare First Folio of 1623, and they jointly signed the famous letters to the noble patrons and "the great variety of readers" that preface the volume.

(Fk. C. B.)

**CONDENSATION TRAIL** (CONTRAIL), an artificial cloud of roughly tubular form, composed of liquid drops or ice crystals usually produced by the sudden condensation of water vapour emitted in the exhaust of aircraft engines. Short-lived trails may also be formed by the rapid cooling of atmospheric water vapour subjected to expansion effects near propeller tips or near wing tips. For each gram of typical fuel burned in the engine, about 1.4 g. of water vapour and about 10,000 cal. of heat are produced by combustion processes and are exhausted into the wake of the aircraft.

Saturation vapour pressure of water vapour depends upon temperature in such a way that the heating effect will not overcome the humidification effect if the aircraft is flying in air colder than about  $-60^{\circ}\text{C}$ . or  $-75^{\circ}\text{F}$ . Hence, a wake of supersaturated vapour is left behind, and in this narrow wake the condensation trail rapidly forms.

The advent of jet-powered aircraft operating in the cold upper atmosphere made this a much more commonly observed phenomenon than it was formerly, except in cold polar regions.

(J. E. McD.)

**CONDENSED MILK:** *see* FOOD PRESERVATION.

**CONDENSER.** The term condenser is ordinarily employed to designate a device for condensing a gas into a liquid. Other types of condensers, however, are also extensively employed. In electrical circuits condensers are used for concentrating opposite electrical charges on plates (*see* CAPACITOR) and in optics condensers are used for concentrating light in order to secure powerful illumination of a slide or other object. The term condenser is also used in the textile industry to denote an apparatus which duffs the web from carding machines and separates it into slivers of soft yarn.

Condensers are employed in power plants for the condensation of exhaust steam from turbines and in refrigeration plants for the condensation of refrigerant vapours such as the Freons or ammonia. They are also employed in the petroleum and chemical industries for the condensation of hydrocarbons and other chemical vapours.

**Steam Condensers.**—In a power plant steam generated in a boiler exhausts from the turbine into a condenser where its latent heat is removed by means of water flowing inside tubes around which the steam condenses. The condenser performs two important functions: (1) it creates a low-pressure region into which the steam can exhaust; (2) it provides a means of collecting the condensed steam (condensate) so that it can be reused in the boiler without further chemical treatment.

The first of the above functions is important since by exhausting steam into a condenser capable of maintaining a low back pressure, approximately 50% more power can be obtained than would otherwise be available. The second function is important since all new water fed to the boiler must be chemically treated to assure a high degree of purity. By reclaiming the condensate only sufficient raw water need be treated to make up for leaks and other steam losses from the cycle. This function means that when a condenser is employed only 1% or 2% of the water fed to the boiler needs to be treated whereas, if a condenser were not employed, all feed water would require treatment.

Steam condensers may be grouped into two major classifications, surface condensers and direct-contact condensers. In surface condensers the condensing steam does not come into direct contact with the cooling water but is separated from it by the walls of the tubes through which the water flows. In direct-contact con-

FIG. 1.—TWO-PASS STEAM CONDENSER

condensers the cooling water is sprayed into the steam and intermingles with it, causing condensation.

The essential features of a surface condenser are illustrated in fig. 1. The unit shown consists of a circular or oval-shaped cylindrical shell into which the exhaust steam flows. Passing through the shell are many small tubes through which relatively cold water flows. Steam coming into contact with the cool surface of the tubes condenses and is collected in a chamber underneath the tubes called the hot well. From there it is removed by condensate pumps. In large condensers air tends to leak into the steam space and provisions must be made to remove this by means of special steam-operated pumps called ejectors (see EJECTOR).

Surface condensers of many shapes and sizes have been built. The smallest will handle only a few pounds of steam per hour while the largest may handle as high as 1,000,000 or more pounds per hour. The latter are found in large central station power plants.

Direct-contact steam condensers may be of either the barometric or jet type. In the barometric type the steam is directed into a chamber into which large quantities of water are sprayed. The water coming into contact with the steam condenses it and tends to create a vacuum because of the collapse of volume of the steam. In order to maintain this vacuum the water discharged from the condenser is directed into a long vertical pipe, called the tailpipe, which extends downward into a lake, stream or other body of water. The low pressure in the condensing chamber causes the water level to rise in the tailpipe and to maintain a level approximately 30 ft. above that of the body of water. The tailpipe thus serves as a pressure seal between the surrounding atmosphere and the condensing steam inside the spray chamber.

Jet-type condensers operate on the same principle as the barometric except that the low pressure in the mixing chamber is maintained by entraining the condensing steam in a high-velocity jet which at the outlet is reduced in velocity and increased in pressure to atmospheric by means of a divergent discharge passage.

Jet and barometric condensers are no longer extensively used because the condensed steam becomes contaminated by the cooling water and thus cannot be reclaimed for further use without chemical treatment.

**Refrigeration Condensers.**—In vapour-compression refrigeration systems the refrigerant gas, after being compressed in a

refrigeration compressor, is liquefied in a refrigeration condenser. During the liquefaction process heat is rejected either to air passing over the condenser or to circulating water. The condensed refrigerant is then passed through an expansion valve where it cools to a low enough temperature to absorb heat from the space or compartment to be cooled, causing vaporization of the refrigerant liquid.

The vaporized gas then enters the compressor to begin another cycle. Refrigeration condensers may be of the shell and tube type similar to steam condensers, in which the refrigerant is condensed around tubes through which circulating water or other fluid is passed, or they may consist of a bank of finned tubes containing the refrigerant over which air circulates in order to absorb the latent heat. Evaporative condensers consisting of banks of tubes over which water is allowed to trickle may also be employed. In the latter some of the water trickling over the tubes is vaporized thus absorbing the heat surrendered by the warmer condensing refrigerant.

In addition to steam and refrigeration condensers there are a variety of designs employed in the petroleum and chemical industries. These are used to liquefy hydrocarbons and other chemicals. In some instances condensers are employed for the purpose of separating condensable from noncondensable gases.

**Heat-Transfer Characteristics.**—An important consideration in the design of a surface condenser for power plants is the rate of transfer of heat from the condensing steam to the circulating water. This rate depends upon three factors, namely: (1) the total cooling surface area to which the condensing steam is exposed; (2) the over-all coefficient of heat transfer from condensing steam to circulating water; (3) the mean temperature difference between the condensing steam and the circulating water.

The first item depends upon the number of tubes employed and their length. The second depends upon the resistance to the flow of heat created by the tube walls and the thin films of stagnant fluid on either side of the walls (fig. 2).

The third factor depends upon the difference in temperature between the condensing steam and the water at inlet and exit to the condenser. The rise in temperature of the circulating water as it flows through the tubes is illustrated in fig. 2. The mean temperature difference between the condensing steam and the water can be shown to be given by the mathematical expression:

$$\Delta t_{\text{mean}} = \frac{\Delta t_1 - \Delta t_2}{\log_e \frac{\Delta t_1}{\Delta t_2}}$$

where  $\Delta t_1$  and  $\Delta t_2$  are the temperature difference between the condensing steam and circulating water at inlet and outlet of the condenser, respectively. The heat which can be transferred per hour from the condensing steam to the circulating water will be

$$Q = AU\Delta t_{\text{mean}}$$

where  $A$  = outside surface area of condenser tubes in square feet;  $U$  = over-all coefficient of heat transfer based on the outer surface area of the tubes in British Thermal Units per hour per square foot per  $^{\circ}\text{F}$ .;  $\Delta t_{\text{mean}}$  = logarithmic mean temperature difference between the condensing steam and the circulating water ( $^{\circ}\text{F}$ ).

The weight of steam which can be condensed per hour may then be computed by the expression

$$W = \frac{Q}{h - h_1}$$

where  $h - h_1$  is the latent heat of condensation which must be removed per pound of steam. Methods of obtaining the over-all coefficient of heat transfer  $U$  and the latent heat surrendered per pound of steam  $h - h_1$  are too involved to be considered here and may be found in the references listed.

FIG. 2.—HEAT TRANSFER IN A SINGLE-PASS CONDENSER

**CONDENSER (ELECTRICAL):** see CAPACITOR.

**CONDER, CHARLES** (1868–1909), English artist, whose unique and charming decorative style, in dainty pastoral scenes, won him a certain vogue. The son of a civil engineer, he was born in London, and spent his early years in India. After an English education he went into the government service in Australia, but in 1890 determined to devote himself to art, and studied for several years in Paris, where in 1893 he became an associate of the Société Nationale des Beaux-Arts. About 1895 his reputation as an original painter, particularly of Watteau-like designs for fans, spread among a limited circle of artists in London, mainly connected first with the New English Art club, and later the International society. Conder died on Feb. 9, 1909.

**CONDILLAC, ÉTIENNE BONNOT DE** (1715–1780), French philosopher, important as a psychologist, as a logician, as an economist and as the leading systematic exponent of Locke's principles in France, was born at Grenoble on Sept. 30, 1715, the third son of Gabriel Bonnot, vicomte de Mably. His elder brothers were Jean Bonnot de Mably, *prévôt des maréchaux* for the Lyonnais, and Gabriel (1709–85), abbé de Mably, the well-known political writer. Destined for the church, Condillac was early ordained priest, and the first part of his life was uneventful except for his making the acquaintance of J. J. Rousseau, who in 1740 was employed as a tutor by Condillac's brother Jean. This led to a lasting friendship.

In Paris, however, Condillac came into contact with Denis Diderot and the *encyclopédistes*. The publication of his *Essai sur l'origine des connaissances humaines* (1746) and *Traité des systèmes* (1749) established his position in the literary salons; he was elected a member of the Berlin academy in 1752. The *Traité des sensations* (1754) and the *Traité des animaux* (1755) followed, and in 1758 he was appointed preceptor to the young Ferdinand of Parma (his *Cours d'études pour l'instruction du prince de Parme*, 16 vol., was published in 1775). Returning to France in 1767, he was elected to the Académie Française in 1768. He published *Le Commerce et le gouvernement considérés relativement l'un à l'autre* in 1776; but the irreligious tone of Parisian intellectual society was offensive to him, and he spent the latter part of his life in retirement at Flux, near Beaugency, where he had purchased a house for his niece in 1773. He died during the night of Aug. 2–3, 1780. *La Logique* (1780) and *La Langue des calculs* (1798) appeared posthumously.

**Psychology.**—Voltaire had made Locke's philosophy fashionable in France, but it was Condillac who established it systematically in that country. In setting forth his empirical sensationism, Condillac shows many of the best qualities of his age and of his nation—lucidity, brevity, moderation and an earnest striving after logical method. Nevertheless, in the analysis of the human mind on which his fame chiefly rests, he omits the active and spiritual side of human experience. His first book, the *Essai sur l'origine des connaissances humaines*, keeps close to his English master. He accepts with some indecision Locke's deduction of our knowledge from two sources, sensation and reflection, and, unlike Locke, uses as his main principle of explanation the association of ideas.

His next book, the *Traité des systèmes*, is a vigorous criticism of metaphysical systems. His polemic, which is inspired throughout with the spirit of Locke, is directed against the innate ideas of the Cartesians, Nicolas Malebranche's faculty psychology. Leibniz' monadism and pre-established harmony, and, above all, against the conception of substance set forth in the first part of the *Ethics* of Spinoza.

The most important of Condillac's works is the *Traité des sensations*, in which he questions Locke's doctrine that the senses give us intuitive knowledge of objects—that the eye, for example, judges naturally of shapes, sizes, positions and distances. To clear up such questions we must study our senses separately, distinguishing precisely what ideas we owe to each sense and observing

how the senses are trained and how one sense aids another. The result, he is confident, will show that all human faculty and knowledge are transformed sensation only, to the exclusion of any other principle, such as reflection. The plan of the book is that the author imagines a statue organized inwardly like a man, animated by a soul which has never received an idea, into which no sense impression has ever penetrated. He then unlocks its senses one by one, beginning with smell, as the sense that contributes least to human knowledge. At its first experience of smell the consciousness of the statue is entirely occupied by it; and this occupancy of consciousness is attention. The statue's smell experience will produce pleasure or pain; and pleasure and pain will thenceforward be the master principle which, determining all the operations of its mind, will raise it by degrees to all the knowledge of which it is capable. The next stage is memory, which is the lingering impression of the smell experience upon the attention: "memory is nothing more than a mode of feeling." From memory springs comparison: the statue experiences the smell, say, of a rose while remembering that of a carnation; and "comparison is nothing more than giving one's attention to two things simultaneously." And "as soon as the statue has comparison it has judgment." Comparisons and judgments become habitual and are stored in the mind and formed into series; and thus arises the powerful principle of the association of ideas. From comparison of past and present experiences in respect of their pleasure-giving quality arises desire; it is desire that determines the operation of our faculties, stimulates the memory and imagination and gives rise to the passions. The passions, also, are nothing but sensation transformed. So runs the argument in the first section of the treatise. In the second section Condillac invests his statue with the sense of touch, which first informs it of the existence of external objects. In a very careful and elaborate analysis, he distinguishes the various elements in our tactile experiences—the touching of one's own body, the touching of objects other than one's own body, the experience of movement, the exploration of surfaces by the hands; he traces the growth of the statue's perceptions of extension, distance and shape. The third section deals with the combination of touch with the other senses. The fourth section deals with the desires, activities and ideas of an isolated man who enjoys possession of all the senses; and ends with observations on a "wild boy" who was found living among bears in the forests of Lithuania. The conclusion of the whole work is that in the natural order of things everything has its source in sensation and yet that this source is not equally abundant in all men; and, finally, that man is nothing but what he has acquired: all innate faculties and ideas are to be swept away.

It is obvious enough that Condillac's naturalistic psychology, with its explanation of personality as an aggregate of sensations, leads straight to atheism and determinism. There is, however, no reason to question the sincerity with which he repudiates both these consequences. What he says upon religion is always in harmony with his profession; and he vindicates the freedom of the will in a dissertation that has very little in common with the *Traité des sensations* to which it is appended. The common reproach of materialism should certainly not be made against him. He always asserts the substantive reality of the soul; and in the opening words of his *Essai*, "Whether we rise to heaven, or descend to the abyss, we never get outside ourselves—it is always our own thoughts that we perceive," is found the subjectivist principle that had formed the starting point of Berkeley.

Condillac did notable work in the direction of making psychology a science. His method of imaginative reconstruction, however, in spite of his protests against abstraction, hypothesis and synthesis, is in the highest degree abstract, hypothetical and synthetic.

**Logic.**—Condillac was an original logician who emphasized the dependence of reasoning on language and analyzed language as a system of signs ultimately derived from natural sounds and gestures. He stressed the importance for science of a well-made language and held that mathematical calculation is the ideal or model for all language.

**Economics.**—In *Le Commerce et le gouvernement* Condillac came forward as an original economist, arguing that value depends not on labour but on utility: "Our needs give rise to value, our exchanges give rise to price."

**Influence.**—Condillac's psychological doctrine, so congenial to the intellectual climate of 18th-century France, was the foundation of the movement known as *Idéologie* and reigned in the French schools for more than 50 years, challenged only by a few, such as Maine de Biran, who saw that it gave no sufficient account of volitional experience.

In the 19th century, however, when German romanticism had spread to France, Condillac's sensationism was superseded by the eclecticism of Victor Cousin. Its effect on English thought is to be discerned in the works of James and John Stuart Mill, of Alexander Bain and of Herbert Spencer, in connection with the association of ideas, with the supremacy of pleasure and pain and with the general interpretation of all mental contents as sensations or transformed sensations.

**BIBLIOGRAPHY.**—For Condillac's works see the *Oeuvres philosophiques de Condillac*, ed. by G. le Roy, 3 vol. (1947–51); also the *Treatise on Sensations*, Eng. trans. by G. Carr (1930). For letters see H. Bédarida (ed.), *Condillac à Parme: quelques lettres inédites* (1924); and G. le Roy (ed.), *Condillac: lettres inédites à Gabriel Cramer* (1953). See further V. Cousin, *Cours de l'histoire de la philosophie moderne*, 1st series, vol. iii (1829); J. P. Damiron, *Mémoires pour servir à l'histoire de la philosophie au dix-huitième siècle*, vol. iii (1864); L. Dewaule, *Condillac et la psychologie anglaise contemporaine* (1892); G. de Baguenault de Puchesse, *Condillac; sa vie, sa philosophie, son influence* (1910); R. Lenoir, *Condillac* (1924); Z. Schaupp, *The Naturalism of Condillac* (1926); G. le Roy, *La Psychologie de Condillac* (1937). (H. Sr.; H. B. A.)

**CONDITION**, a stipulation, a provision that needs to be satisfied (from Lat. *condicio*, "something agreed upon or arranged"). Also, something that must exist or be the case or happen in order for something else to exist or be the case or happen (as in "the will to live is a condition for survival"). In a different set of senses, the word means a state or circumstance or mode of being (as in "the poor condition of the soil").

In logic, a sentence or proposition of the form "If *A* then *B*" (or, in symbols,  $A \supset B$ ) is called a conditional (sentence or proposition). Similarly, "Whenever *A* then *B*" [or, in symbols,  $(x) \cdot A(x) \supset B(x)$ ] may be called a general conditional. In such uses, "conditional" is a synonym for "hypothetical" and is opposed to "categorical." Closely related in meaning are the common and useful expressions, "sufficient condition" and "necessary condition." Suppose some instance of a property, *P*, is always accompanied by a corresponding instance of some other property, *Q*, but not necessarily vice versa; then *P* is said to be a sufficient condition for *Q* and, equivalently, *Q* is said to be a necessary condition for *P*. Thus a severed spinal column (or the property of having such) is a sufficient, but not a necessary, condition for death; while lack of consciousness is a necessary, but not a sufficient, condition for death. In any case where *P* is both a necessary and a sufficient condition for *Q*, the latter will also be a necessary and sufficient condition for the former, each instance of either property being regularly accompanied by a corresponding instance of the other. The terminology has no reference to the temporal relations, if any, of the corresponding instances, and is also applicable to logical or mathematical or other nontemporal properties. Thus, it is proper to speak of "a necessary condition for the solution of an equation" or "a sufficient condition for the validity of a syllogism." (M. Bk.)

In philosophy the above uses of the term condition have led to the contrast between "conditioned" and "absolute" being (or "dependent" versus "independent" being). Thus all finite things exist in certain relations not only to all other things, but possibly also to thought; in other words, all finite existence is "conditioned." Hence Sir William Hamilton speaks of the "philosophy of the unconditioned," i.e., of thought in distinction to things which are determined by thought in relation to other things (see *ABSOLUTE*). An analogous distinction is made (cf. H. W. B. Joseph, *Introduction to Logic*, p. 380 ff.) between the so-called universal laws of nature and conditional principles which, though they are regarded as having the force of law, are yet dependent or

derivative, i.e., cannot be treated as universal truths. Such principles hold good under present conditions, but other conditions might be imagined under which they would be invalid; they hold good only as corollaries from the laws of nature under existing conditions.

**CONDITIONING**, a term used in the sciences of behaviour to designate a process whereby a response becomes more frequent or more predictable in a given environment as a result of reinforcement. The history of this concept shows its dependence upon experimental techniques for the study of reflexes. Physiologists in Russia, England and the United States contributed the original procedures, observations and definitions. After the 1920s psychologists carried on the larger share of experimental work on the nature and prerequisites of conditioning.

Conditioning is a form of learning in which either (1) a given stimulus (or signal) becomes increasingly effective in evoking a response or (2) a response occurs with increasing regularity in a well-specified and stable environment. The type of reinforcement that is used determines which of these consequences obtains. When two stimuli are presented in an appropriate time and intensity relationship, one of them will come to induce a response resembling that of the other. The process can be described as one of stimulus substitution. This procedure is called classical (or respondent) conditioning. In the traditional technique of Russian laboratories, a dog is placed in a harness within a sound-shielded room. On each conditioning trial the sound of a bell or a metronome is promptly followed by food powder blown by an air puff into the dog's mouth. Here the tone of the bell is known as the conditioned (or sometimes conditional) stimulus, abbreviated as CS. The salivation to this sound is the conditioned response (CR). The strength of conditioning is measured in terms of the number of drops of saliva secreted during test trials in which food powder is omitted. The original response of salivation to introduction of food into the mouth is called the unconditioned response (UR) to food (the US). Using a variety of stimuli and responses, psychologists in the United States have shown that in man and other mammals there is a very consistent optimum interval between the CS and the US which the experimenter may utilize. This interval is approximately half a second. For cold-blooded animals, the optimum interval for conditioning is longer. In fish, for example, the CS may best precede the US by 1½ seconds. When the CS is appropriately followed by the US, reinforcement is said to occur. If the US is omitted on any trial or series of trials the procedure is referred to as extinction.

Instrumental (or operant) conditioning differs from classical conditioning in that reinforcement occurs only after the organism executes a predesignated behavioural act. No US is used to initiate the specific act to be conditioned. Here the required behaviour is known as an operant or, once it occurs with regularity, also as a conditioned response, to correspond to its counterpart in classical conditioning.

**History.**—The psychic reflex was observed in the 18th century by Robert Whytt, who noted that salivation was accelerated by the sight or even by the ideational recall of food. The fundamental fact of conditioning was observed in the United States by E. B. Twitmyer, who developed a knee-jerk conditioned reflex in a human subject in 1902. The modern development of conditioning in both fact and theory, however, is commonly associated with the name of I. P. Pavlov (q.v.), who devoted the last 36 years of his life to these researches. V. M. Bekhterev (1857–1927), a countryman of Pavlov, also played an important role. Both acknowledged their indebtedness to Ivan Sechenov, who outlined in 1865 a comprehensive reflex theory of behaviour.

The translation in 1913 of Bekhterev's book into French and German was important in arousing the interest of U.S. psychologists, most of whom preferred his motor method to Pavlov's salivary technique. Although "it is probably more to him than to Pavlov that we owe the bold acceptance of conditioning by psychologists" (E. R. Hilgard), Pavlov's terminology and conceptual system were more widely adopted.

In the United States objective psychology had already won appreciable support prior to the advent of conditioning. Backed by

the concepts of association and habit, J. B. Watson (*q.v.*), initially interested in animal behaviour, founded an objective psychology in 1913. He exploited conditioning as a substitute for introspection, using Pavlov's term (conditioned reflex) superimposed upon Bekhterev's type of motor-conditioning procedure. Watson was largely responsible for the incorporation of conditioning into U.S. psychology.

The early enthusiasm for conditioning in the U.S. was largely verbal. During the decade beginning with 1926, conditioning played a less conspicuous role in textbooks but was given more serious attention in the laboratories. The translation of Pavlov's major work into English in 1927 catalyzed research interest, and a mature theoretical framework was eventually constructed by C. L. Hull (*q.v.*) in an attempt to bridge the gap from conditioning to more complex forms of learning.

After the publication of B. F. Skinner's *The Behavior of Organisms* in 1938, the use of operant conditioning procedures became extensive. Specific techniques have varied somewhat from organism to organism. Although more commonly applied to the experimental study of animal behaviour, the method of operant conditioning also has been applied by Skinner and others in human behavioural experimentation. A. G. Ivanov-Smolensky reported his observations with this method in 1927 as he used it in studies of discriminatory learning in children. Chocolate candy constituted the primary reinforcement for these experiments.

**Definitions and Methods.**—Higher-order conditioning can be established on the basis of preceding conditioned responses. If tone is combined with food, a first-order salivary CR is developed. If this tone is then combined with light, the salivary response can eventually be evoked by light alone (second-order CR). Pavlov was unable to go beyond the second order by the salivary method and the third order by the motor method. Later work employing combinations or sequences of classical and operant conditioning techniques showed that conditioning can be extended at least to the fifth order.

By applying an unconditioned stimulus (food) at the end of a one-minute presentation of the conditioned stimulus (tone) a delayed CR will be developed, conditioned salivation being deferred until near the time for administration of food. Similarly, if the tone is presented for only 10 or 15 seconds, followed by food 45 seconds after cessation of tone, a trace CR will appear nearly one minute after onset of tone. This illustrates, according to Pavlov, internal inhibition, since there must be some internal trace inhibiting salivation during the period of silence. If a distracting influence, such as a loud or unusual sound, is applied during the interval, there will be inhibition of inhibition and salivation will occur at once.

If during the initial training period the conditioned stimulus is a tone of 1,000 cycles, many other tones will at first evoke the CR. This is known as sensory generalization. With continued training, specialization or differentiation will develop so that the CR is eventually evoked only by the particular tonal frequency used for conditioning. The process is more effectively developed by alternate trials with other tones which are not reinforced with food or shock. This technique is regularly used in the study of the limits of discriminative capacity in the experimental animal. When the organism is forced beyond its capabilities, experimental neurosis may result (*see* NEUROSES, EXPERIMENTAL).

Virtually any response is conditionable, subject only to the experimenter's ingenuity and to the organism's repertoire of reflexes. Bekhterev's method has been used with a variety of responses (eyelid and knee-jerk reflexes, withdrawal movements of various types). The responses controlled by the autonomic nervous system have likewise been explored; *e.g.*, salivation, pulse, blood pressure, skin resistance (perspiration), gastrointestinal secretions, nausea and diuresis. Even the conditioning of immunity reactions has been reported, but these data are equivocal. In human subjects, autonomic responses have been conditioned to verbal stimuli such that vasomotor and pupillary changes are produced by voluntarily thinking of the stimulus word.

Experimental extinction may be induced by repeatedly applying the conditioned stimulus without reinforcement until the CR no

longer appears. This process is analogous to negative adaptation or habituation, but the decrement is also explicable in terms of interference, in which a new response works to obliterate the old CR. Extinction suggests but may not be identical with human verbal forgetting. When the CR has just been extinguished, it can be readily reinstated with a few reinforced trials; the learned pattern was not "forgotten" but lacked motivation. The unconditioned stimulus apparently has two functions: that of evoking the required response (*e.g.*, salivation, paw flexion) and also that of offering the requisite motivation (E. A. K. Culler).

One experiment will illustrate this principle. The sound of a bell followed by stimulation directly applied to the motor cortex of the brain (thereby evoking paw flexion) will not set up a CR to the bell unless the dog is motivated (*e.g.*, sensory shock, food). Likewise the animal will seldom establish a flexion CR, however often its leg is passively flexed, unless motivation is provided (*e.g.*, food or a pat on the head). It is also possible, however, that with sufficient overlearning the CR may be susceptible to extinction no more or less readily than human verbal forgetting.

Conducive (perhaps requisite) to conditioning is a prepotent unconditioned stimulus. Although a bright light will produce sharp pupillary constriction, this stimulus can be combined with an even stronger agent (electric shock) so that the initial constriction is followed by dilation while the light is still on. This occurs because the startle reaction to shock, which includes pupillary dilation, is biologically prepotent over the pupillary reflex to light.

A fear CR developed in children to the sight of a rabbit (by paired combinations with loud noise) may be extinguished by presenting the rabbit in conjunction with cookies or candy. This method of reconditioning has had application in clinical practice, for example, in curing enuresis, but requires considerable skill in manipulating the conditions. Injudicious application of the stimuli, as in the fear CR to the rabbit, may not only fail to eliminate the fear but may instead expand the CR so as to incorporate the sight of cookies or candy into the pattern to the extent of producing nausea.

**Neurological Correlates.**—Pavlov's work was largely applied in the U.S. to the development of a behavioural theory of learning, but he was himself primarily concerned with the dynamics of the cerebral processes which he inferred from his conditioning data. Criticism has been directed at specific concepts such as irradiation, which was postulated as the cerebral mechanism underlying generalization. His basic presupposition that the locus of conditioning is exclusively cortical, upon which his theory of vicarious cortical function largely depended, was proved erroneous. Following his early report of negative results with one animal, a number of investigators were able to establish conditioned reflexes in totally decorticated cats and dogs. In one of these animals a simple discrimination was established between two auditory stimuli. CR's have also been established in organisms lacking true neocortex, and D. P. Marquis developed a feeding response to the sound of a buzzer in human infants only ten days old, at which time the cerebral cortex is presumed to be nonfunctional.

The sensory systems are synaptically integrated at several levels in the cerebrum with available associative centres and motor outlets. In the cat, CR to acoustic stimuli can be mediated at the collicular and bulbar levels (primitive brain centres). One group of experimenters reported that conditioning and extinction can be obtained with only spinal cord innervation in young cats and dogs. This suggests, as seems theoretically plausible, that any synaptic apparatus can mediate simple modifications in behaviour.

The role of the cerebral apparatus is being studied in connection with a variety of functions. Some mechanisms are solely a function of the cortex; permanent deficit follows extirpation of the appropriate cortical system. Other functions are maintained simultaneously at a subcortical level so that no appreciable loss follows cortical intervention. In other instances, although disruption of function follows cortical ablation, restitution results from postoperative training. In the last example it may be presumed that the function is normally mediated by cortical patterns, but that it may also be established and maintained, in their absence, by subcortical mechanisms.

The brain has been shown to respond with massive pulses of electrical potential when rhythmically stimulated, as with a flickering light. Using an initially neutral sound as a signal, followed repeatedly by flicker, F. Morrell and H. Jasper conditioned this driven brain rhythm so that it appeared a few seconds after the sound was given alone. The conditioning process was seen to develop through several intermediate stages involving both generalized and local activation within receiving areas of the brain. That such a massive participation of neural elements should be susceptible to conditioning was evidence that a reflexive neural switching theory may be too simple.

Much research has been directed to a determination of the essential components for conditioning in the arc from sense organ to motor response. In one experiment with electrodes implanted in the animal's brain, shock stimulation of the sensory cortex (conditioned stimulus) followed by normal shock to paw resulted in a CR, indicating that the sensory component of the conditioned stimulus was dispensable. Conditioning does not occur if the unconditioned response is produced by directly stimulating the effectors. Injection of pilocarpine causes increased salivation, but paired combinations of drug injections with an indifferent stimulus will not produce a salivary CR (N. Kleitman). When the neural apparatus is affected, as with morphine injections, a salivary as well as a more general nausea CR is readily established (G. Crisler). With respect to the motor component of the neurally innervated unconditioned response, W. H. Gantt concluded that actual limb flexion is not required in order to establish a limb-flexion CR. This study was repeated and was criticized because responses during training were possible in the other, nonparalyzed limbs (W. N. Kellogg). In a different approach, all striated musculature was paralyzed with curare during training. After recovery of muscular function the CR was restricted to autonomic components such as pulse and blood pressure (E. Girden), suggesting that, at least during the initial training, some activity by the conditioning reflex is required. This is known as the response theory. These researches provided answers by no means definitive, nor did they necessarily represent the most promising avenue in the study of such problems. There are theoretical formulations, some of which are basically conditioning concepts, that emphasize not the role of the peripheral components but depend upon synaptic switching in the cerebral apparatus.

In addition to the discriminative and associative mechanisms, the motivational properties of intracranial electrical stimulation also have been observed. The effort to find those brain centres whose activation constitutes the energizing component in conditioning has been successful (J. M. R. Delgado, J. Olds and P. Milner and others). Electrodes placed in discrete centres of the thalamus, hypothalamus or midbrain were used in place of rewards or punishment in the reinforcement of conditioning, both classical and instrumental. Rats and monkeys learned to give themselves electrical stimulation in "pleasure" centres by pressing a lever. Stimuli presented in conjunction with the electrical or chemical activation of other centres were subsequently used to produce second-order escape and avoidance learning. Some aspects of the neurochemical basis for emotional behaviour were demonstrated and anatomical relations mapped in these experiments. One important contribution attempted to encompass all the psychological processes, including learning, perceiving and emotions. This theory assumed the development of a three-dimensional lattice of "cell assemblies" in the cortical association areas of the cerebrum under repeated stimulations of the organism (D. O. Hebb). A full treatment of this proposal here would necessarily lead into a discussion of nonreflexological theories of neural integration (e.g., field theory of cerebral activity as proposed by the Gestalt psychologists), which is clearly beyond the scope of the immediate discussion.

Finally, attention should be called to the somewhat related and basic problem of retention which still largely, if not completely, resisted understanding in the 1960s. An examination of the question of what occurs in the structure while learning takes place inevitably leads to the issue of how the organism retains, or remembers, what is experienced.

Traditional theories include, among others, the law of effect (E. L. Thorndike) and the drainage principle (W. McDougall). An early suggestion by C. U. A. Kappers, which proposed that retention is due to actual neural growth of neuronic endings during repeated stimulations, was being revived (Hebb). Another suggestion (J. J. Katz and W. C. Halstead) made use of the well-known structural complexity and modifiability of protein molecules. Evidence for the central role of proteins in nerve-cell chemistry added plausibility to this proposal.

**Evaluation.**—As a method, conditioning is an unsurpassed technique for precise measurement of sensory capacity (absolute and differential thresholds) in animals; e.g., hearing. It has been of considerable value in the investigation of the cerebral correlates of behaviour. It has also been useful in studies of the effect of drugs, experimentally produced neurosis and even personality differences in animals. It has had some success in the study of emotional behaviour (fears) and has been clinically applied in the treatment of some specific maladjustments.

The Pavlovian inferences concerning cerebral dynamics as well as his behavioural hypotheses attracted staunch defenders as well as severe critics. While a number of his theories proved to be untenable, behaviourism later evolved a more mature theoretical formulation (K. W. Spence). Even as an indirect influence, the development of opposed theoretical views enriched science; to some extent, the history of Gestalt psychology is a reaction to reflexology.

Furthermore, of no small importance was the development of what is recognized as the organismic approach, in psychology, psychiatry and medicine, as contrasted with the older, primitive and even animistic mentalism. To this, objective psychology and reflexology also made their contribution. See ANIMAL BEHAVIOUR; BEHAVIOURISM; LEARNING; PSYCHOLOGY, COMPARATIVE; PSYCHOLOGY, EXPERIMENTAL; REFLEX. See also references under "Conditioning" in the Index volume.

(E. G.; A. H. R.)

**CONDOMINIUM**, the joint possession by two or more states of sovereignty over a territory, with a specified division among them of the powers of government. An arrangement of this nature is usually set up by treaty; often, but not always, it represents a compromise solution to a dispute over a territory, agreeable to all disputants. The U.S.-British condominium over the islands of Canton and Enderbury in the Pacific ocean, for instance, was created in 1939 to terminate a diplomatic contest for exclusive title. Prominent among condominiums was that established in 1899 for the Sudan by Great Britain and Egypt, under which the flags of both were used in the territory and the governor general was appointed by the khedive with the approval of the British government; in 1956 the Sudan became independent. A list of historic condominiums would include, among others, Schleswig-Holstein under Austria and Prussia (1864-66); the Samoan Islands under the United States, Great Britain and Germany (1889-99); and Egypt under Great Britain and France (1879-52). Although the occupation system for Germany after 1945 was occasionally called a condominium, strictly it was not one, for German sovereignty was understood to be only interrupted and terminated, during the years of government by the United States, Great Britain, France and the Soviet Union.

See A. A. El-Erian, *Condominium and Related Situations in International Law* (1952).

**CONDOR**, a South American vulture (*Vultur gryphus*), one of the largest of existing birds of flight, about four feet in length

CARL D. KOPFORD FROM NATIONAL AUDUBON SOCIETY

CALIFORNIA CONDOR (*GYMNOGYPS CALIFORNIANUS*) IN FLIGHT

and nine feet between the tips of its wings, but large specimens span ten feet or more. The head, flattened above, and the neck are devoid of feathers. In the male the head has a caruncle or comb and the skin of the neck forms a wattle. The adult plumage is a uniform black, with the exception of a fringe of white feathers nearly surrounding the base of the neck, and patches of white in certain wing feathers. The middle toe is greatly elongated, and the hinder one only slightly developed. The talons are comparatively straight and blunt. The female, contrary to the usual rule among birds of prey, is smaller than the male.

The condor is a native of the Andes, from the Strait of Magellan to latitude 4° N., where its favourite haunts are at elevations of 10,000 to 16,000 ft. There, during February and March, on inaccessible ledges of rock, it deposits two white eggs, from three to four inches in length, in a nest consisting merely of a few sticks. Incubation lasts for seven weeks, and the young are covered with a whitish down until they are almost as large as their parents. They do not fly well until a year old.

Condors feed on carrion, but may attack sheep, goats and deer. They are exceedingly voracious, feeding in the morning and evening. When gorged with food, they are sluggish and may then be more readily caught. They sleep during the greater part of the day, and hunters may climb the trees on which they roost, noosing them before they wake. In flight the condor is remarkably graceful. The birds flap their wings on rising from the ground, but after attaining a moderate elevation they seem to sail on the air with motionless wings.

The California condor (*Gymnogyps californianus*) is found in the coast ranges of southern California from Monterey bay to Lower California. It has white underwing coverts, with a wing-spread of ten feet. It is somewhat larger than the condor of South America, though of less heavy build.

(Ht. FN.)

**CONDOR, CORDILLERA DEL**, one of the eastern ranges of the Andes, about 160 mi. long, lying mostly in Ecuador, about 60 mi. S.E. of Cuenca city. A number of tributaries of the Santiago and Cenepa rivers rise there. The Cordillera lies close to the southeastern Ecuador-Peru boundary, a disputed area since colonial days. The Cenepa river, discovered by the U.S. army air force when it was mapping the area, played an important role in the final stages of the border issue, for the 1942 protocol drew the border between the two nations along a presumably uninterrupted water divide. The air force map divulged the interposing Cenepa valley.

**CONDORCET, MARIE JEAN ANTOINE NICOLAS DE CARITAT**, MARQUIS DE (1743-1794), French mathemati-

cian, philosopher and revolutionary, whose ideas of progress greatly influenced 19th-century philosophy and sociology, was born at Ribemont, in Picardy, on Sept. 17, 1743. He was descended from the ancient family of Caritat, who took their title from Condorcet in Dauphiné. He was educated at the Jesuit college in Reims and at the Collège de Navarre in Paris, where he showed his first promise as a mathematician. In 1769 he became a member of the Academy of Sciences, to which he contributed papers on mathematical and other subjects.

He was the friend of almost all the distinguished men of his time and a zealous propagator of the religious and political views then current among French men of letters. He was induced by D'Alembert to take an active part in the preparation of the *Encyclopédie*. He was elected to the perpetual secretaryship of the Academy of Sciences in 1777 and to the French Academy in 1782 and was a member of other European academies. In 1785 he published his *Essai sur l'application de l'analyse à la probabilité des décisions rendues à la pluralité des voix*, a remarkable work which has a distinguished place in the history of the doctrine of probability; a second edition, greatly enlarged and completely recast, appeared in 1805 under the title of *Éléments du calcul des probabilités et son application aux jeux de hasard, à la loterie, et aux jugemens des hommes*. In 1786 he married Sophie de Grouchy (1764-1822; a sister of Emmanuel de Grouchy, the future marshal), said to have been one of the most beautiful women of her time. Her *salon* at the Hôtel des Monnaies, where Condorcet lived in his capacity as inspector general of the mint, was one of the most famous of the time.

Condorcet published his *Vie de M. Turgot* in 1786 and his *Vie de Voltaire* in 1789. Both works were widely and eagerly read and are perhaps, from a purely literary point of view, the best of Condorcet's writings.

The outbreak of the Revolution, which he greeted with enthusiasm, involved him in a great deal of political activity. He was elected to represent Paris in the Legislative Assembly and became its secretary. He was active in the reform of the educational system. He was chief author of the address to the European powers (Dec. 29, 1791); and on April 21 and 22, 1792, he presented a scheme for a system of state education, which was the basis of that ultimately adopted. Condorcet was one of the first to declare for a republic and drew up the declaration justifying the suspension of the king and the summoning of the National Convention (Aug. 1792). In the convention he represented the *département* of Aisne and was a member of the committee on the constitution. His draft (presented Feb. 15, 1793), however, was rejected in favour of that of the Jacobins. In the trial of Louis XVI he voted against the death penalty. But his independent attitude was becoming dangerous, and his opposition to the arrest of the Girondists (June 1793) led to his condemnation and outlawry.

To occupy his mind while he was in hiding, some of his friends prevailed on him to engage on the work by which he is best known, the *Esquisse d'un tableau historique des progrès de l'esprit humain*. Other works were written at the same time, including the *Avis d'un père proscrit à sa fille*. Some of them were published by friends at the time and others were issued after his death. Still interested in public affairs and believing that the house in which he had been hiding was watched, he escaped and, after hiding in thickets and quarries for three days, entered the village of Clamart on the evening of March 27, 1794. His appearance betrayed him, and he was taken to Bourg-la-Reine and imprisoned. On the morning of March 29 he was found dead, whether from exhaustion or by poison is unknown.

Mme de Condorcet divorced her husband (having obtained his consent) during his proscription and succeeded in regaining possession of the family property, which had been confiscated by Robespierre's government. She lived for a time with J. J. Mailla Garat (nephew of Joseph Garat the *idéologue*) and later with Claude Fauriel, the philologist, who outlined her. She translated Adam Smith's *Theory of the Moral Sentiments* into French (1798; with her own *Huit lettres sur la sympathie* appended) and co-operated in editing the complete works of her husband, 21 vol.

(1804). Her *salon* was a meeting place of those opposed to Napoleon's autocratic regime. She died in Paris on Sept. 8, 1822.

**Philosophy.**—Condorcet's philosophical fame rests chiefly on the *Esquisse*, which was first published posthumously in 1795 (Eng. trans. by June Barraclough, *Sketch for a Historical Picture of the Progress of the Human Mind*, with an introduction by Stuart Hampshire, 1955). Its fundamental idea is that of the continuous progress of the human race to an ultimate perfection. He represents man as starting from the lowest stage of barbarism with no superiority over the other animals save that of bodily organization and as advancing uninterruptedly at a more or less rapid rate in the path of enlightenment, virtue and happiness.

The stages which the human race has already gone through, or, in other words, the great epochs of history, are regarded as nine in number. The first three can confessedly be described only conjecturally from general observations as to the development of the human faculties and from the analogies of savage life.

In the first epoch, men are united into hordes of hunters and fishers, who acknowledge in some degree public authority and the claims of family relationship and who make use of an articulate language.

In the second epoch—the pastoral state—property is introduced and along with it inequality of conditions and even slavery, but also leisure to cultivate intelligence, to invent some of the simpler arts and to acquire some of the more elementary truths of science.

In the third epoch—the agricultural state—as leisure and wealth are greater, labour better distributed and applied and the means of communication increased and extended, progress is still more rapid. With the invention of alphabetic writing the conjectural part of history closes, and the more or less authenticated part begins.

The fourth and fifth epochs are represented as corresponding to Greece and Rome. The middle ages are divided into two epochs, the former of which terminates with the crusades and the latter with the invention of printing. The eighth epoch extends from the invention of printing to the revolution in the method of philosophic thinking accomplished by Descartes. The ninth epoch begins with that great intellectual revolution and ends with the great political and moral revolution of 1789 and is illustrious, according to Condorcet, through the discovery of the true system of the physical universe by Sir Isaac Newton, of human nature by John Locke and the Abbé de Condillac, and of society by Turgot, Richard Price and Jean Jacques Rousseau.

There is an epoch of the future—a tenth epoch—and the most original part of Condorcet's treatise is that which is devoted to it. After insisting that general laws regulative of the past warrant general inferences as to the future, he argues that the three tendencies which the entire history of the past shows will be characteristic features of the future are: (1) the destruction of inequality between nations; (2) the destruction of inequality between classes; and (3) the improvement of individuals, the indefinite perfectibility of human nature itself—intellectually, morally and physically. The equality to which he represents nations and individuals as tending is not absolute equality but equality of freedom and of rights. Nations and men, he thinks, are equal if equally free and are all tending to equality because all are tending to freedom.

As to indefinite perfectibility, he nowhere denies that progress is conditioned both by the constitution of humanity and by the character of its surroundings. But he affirms that these conditions are compatible with endless progress and that the human mind can assign no fixed limits to its own advancement in knowledge and virtue or even to the prolongation of bodily life. This theory explains the importance that he attached to popular education, to which he looked for all sure progress. The book is notable for its intense aversion to all religion, especially Christianity, and to monarchy. Pervaded by a spirit of excessive hopefulness, it contains numerous errors of detail, due to the circumstances in which it was written. Its value lies in its general ideas. Condorcet's ethical position gives emphasis to the sympathetic impulses and social feelings and had considerable influence upon Auguste Comte.

**BIBLIOGRAPHY.**—A *Biographie de Condorcet*, by M. F. Arago, is

prefixed to A. Condorcet-O'Connor's edition of Condorcet's works, 12 vol. (1847-49). See J. F. E. Robinet, *Condorcet, sa vie et son oeuvre* (1893); F. **CONDOTTIERE** (plural *condottieri*), an Italian term for the leader of the mercenary military companies, often several thousand strong, which were hired out to carry on the wars of the Italian states. The word is often extended so as to include the soldiers as well as the leader of a company.

The *condottieri* played a very important part in Italian history from the middle of the 13th to the middle of the 15th century. Because of the special political and military circumstances of medieval Italy, and in particular the wars of the Guelphs and Ghibellines, the *condottieri* and their leaders played a more conspicuous and important part in history than the "free companies" elsewhere. Among these circumstances the absence of a numerous feudal cavalry, the relative luxury of city life and the incapacity of city militia for wars of aggression were the most prominent.

From this it resulted that war was not merely the trade of the *condottiere* but also his monopoly, and he was thus able to obtain whatever terms he asked, whether money payments or political concessions. These companies were recruited from wandering mercenary bands and individuals of all nations, and from the ranks of the many armies of middle Europe which from time to time overran Italy.

Montreal d'Albarno, a gentleman of Provence, was the first to give them a definite form. A severe discipline and an elaborate organization were introduced within the company itself, while in their relations with the people the most barbaric licence was permitted. Montreal himself was put to death at Rome by Rienzi, and Conrad Lando succeeded to the command. The Grand Company, as it was called, soon numbered about 7,000 cavalry and 1,500 select infantry, and was for several years the terror of Italy. Its members seem to have been chiefly Germans. On the conclusion (1360) of the peace of Brétigny between England and France, Sir John Hawkwood led an army of English mercenaries, called the White Company, into Italy, where it took a prominent part in the confused wars of the next 30 years.

Toward the end of the century the Italians began to organize armies of the same description. This ended the reign of the purely mercenary company and began that of the seminational mercenary army which endured in Europe till replaced by the national standing army system.

The first company of importance raised on the new basis was that of St. George, originated by Alberigo, count of Barbiana, many of whose subordinates and pupils conquered principalities for themselves. Shortly after, the organization of these mercenary armies was carried to the highest perfection by Muzio Attendolo Sforza, *condottiere* in the service of Naples, who had been a peasant of the Romagna, and by his rival Brancaccio di Montone in the service of Florence. The army and the renown of Sforza were inherited by his son Francesco Sforza, who became duke of Milan (1450).

Less fortunate was another great *condottiere*, Carmagnola, who first served one of the Visconti and then conducted the wars of Venice against his former masters, but at last awoke the suspicion of the Venetian oligarchy and was put to death before the palace of St. Mark (1432). Toward the end of the 15th century, when the large cities had gradually swallowed up the small states and Italy itself was drawn into the general current of European politics and became the battlefield of powerful armies—French, Spanish and German—the *condottieri*, who proved unequal to the gendarmery of France and the improved Italian troops, disappeared.

The soldiers of the *condottieri* were almost entirely heavy armoured cavalry (men-at-arms). They had, at any rate before 1400, nothing in common with the people among whom they

fought, and their disorderly conduct and rapacity seem often to have exceeded that of other medieval armies. They were always ready to change sides at the prospect of higher pay. They were connected with each other by the interest of a common profession and by the possibility that the enemy of today might be the friend and fellow soldier of tomorrow. Further, a prisoner was always more valuable than a dead enemy. In consequence of all this their battles were often as bloodless as they were theatrical and skilful, and splendidly equipped armies were known to fight for hours with hardly the loss of a man.

**CONDUCTING.** In the musical context, conducting is the art of controlling a group of performers in the execution and interpretation of a musical composition, principally by means of silent and partially codified gestures.

These gestures indicate the rhythm and bar-shape (phrasing) of the music, the direction of the beat making immediately apparent to the musicians the number of pulses (beats) to the measure. These beats are normally given by a slender baton held in the conductor's right hand, the left being largely reserved for expression, nuances, entries of the different parts and other subtleties of interpretation. Some conductors, especially in the United States, have, however, developed a technique that dispenses with a baton. This has long been the more usual style in unaccompanied choral conducting where the fact that the number of different parts is limited (each singer, moreover, having a full score of the music) enables the conductor to dispense with many of the formalities of gesture that may be indispensable in a complicated orchestral texture.

**Origins.**—The art of conducting has been pursued in a highly specialized form only since the early 19th century, though its origins are undoubtedly of great antiquity. The earliest positive records of such external control are of the 15th-century custom within the Sistine choir in Rome of beating the pulse of the music with a roll of paper. This practice, whether with paper or with a lengthy pole or baton, seems to have continued and even to have been much abused to the point of becoming grossly audible during actual performance. By the time of Bach and Handel it had become established tradition, especially in Germany, that a composer be appointed to court or chapel who would not only write the music required but be personally in charge of all performances. The act of presiding would generally be carried out by the *Kapellmeister* seated at the organ or harpsichord. This custom was also widely accepted in other countries not only for resident but also for visiting musicians, and it was from the keyboard that Haydn directed the performances of his symphonies at the "Salomon" concerts in London in 1791 and 1794.

In Paris, with its particular requirements for the Opéra, the evolution of the conductor passed from the time thumpers to the concertmaster (or leader, as he has always been called in Great Britain), who controlled the proceedings as best he could from the first violin desk. This custom was also adopted in opera houses in Germany and Italy, though the leader might be responsible only for the orchestra, the singers coming under the jurisdiction of the *maestro al cembalo*, who would probably be seated in the midst of the orchestral musicians. Such divided control led on many occasions to confusion and doubtless precipitated the rise of the conductor who, alone among the performers, made no sound of whatever and whose direction was necessary for the more complicated scores of the middle decades of the 19th century.

**The Modern Conductor.**—Johann Stamitz and Gasparo Spontini had already been responsible for a distinct improvement in the standard of performance. With composer-conductors from Berlioz, Weber and Spohr to Mendelssohn and Wagner following closely upon their heels, the musical scene was quickly transformed. If Berlioz may be regarded as the father figure of modern conducting, it is Wagner and the school of dominating personalities who followed his inspired example of imaginative gesture and control who are the first important conductors in the 20th-century sense of the term. Hans von Bülow, Hermann Levi, Hans Richter, Felix Mottl, Karl Muck and Felix Weingartner were the pioneers of a new tradition in the art of orchestral training to a degree of finesse and sensitivity hitherto undreamed of, and in the exercise

of comprehensive direction vested in a single controller.

As the conductor found his power and prestige rising, so his opportunities grew for influencing the musical taste of the time, and even of changing the course of musical history. Mendelssohn's position of undisputed authority at the Gewandhaus in Leipzig enabled him to inaugurate a revival of the music of Bach, and conductors were also able to play an important part in the promotion and commissioning of contemporary compositions. In his earlier days as a resident German conductor, Richard Strauss did admirable work in the championing of music by his younger contemporaries such as Engelbert Humperdinck and Gustav Mahler. The concerts in Berlin promoted and conducted by Ferruccio Busoni at the beginning of the 20th century were of paramount importance in their presentation for the first time of works by Debussy, Bartók, Sibelius, Elgar, Delius and Nielsen. The name of Serge Koussevitzky stands as an example of enlightened autocracy in this respect during his term as conductor of the Boston Symphony orchestra, his patronage extending at one time to the creation of a publishing house bearing his name. Hermann Scherchen similarly inaugurated an edition devoted to the publication of contemporary music.

As the new standards set and made possible by the baton-wielding conductors influenced the course of musical composition, so in its turn the new music made the tasks of the conductor enormously more varied and specialized. Moreover, apart from the already wide difference of organization and control required in the opera house and the concert hall (the latter now entailing expert flexibility in following the freedom of the modern virtuoso soloist), new factors arose, born of the changes in musical life all over the world. Recording, radio technique, ballet, television opera, the fitting of music to films, and above all the wide variety of styles provided by the more extreme schools of modern composition on the one hand and the music of earlier periods on the other (the latter often entailing much scholarly research)—all these and other tasks of musical direction may enter the conductor's province, requiring specialized knowledge, a thorough understanding of the music and of those who are playing under him, and a highly developed stick technique.

During the years immediately preceding, and between, World Wars I and II the figure of the international conductor was exalted to a remarkable extent. This was in some measure due to the dynamic personalities of many of the men who rose to unprecedented heights in this most far-reaching and demanding of musical careers. Mahler and Arturo Toscanini, for example, became legends for their tyrannical demands in the relentless search for the highest artistic standards.

It was Toscanini who initiated the vogue for conducting from memory, an accomplishment which poor eyesight led him to develop. The undeniably impressive feat of handling a large body of performers in an intricate work entirely without a score has, however, since been exploited for its own sake. This is part of a tendency to throw a spotlight on the conductor as a glamorous figure per se, and considerable controversy has arisen as to the visual part played by the conductor in performance; that is to say, whether he should be demonstrative (thus portraying his reactions to the music to both orchestra and audience in a way which can, at best, enhance greatly the impact of the music) or extremely reserved in manner and gesture lest his antics interfere with the listener's enjoyment and reception.

One thing seems certain: there can be no return to a conductorless orchestra. The interaction upon each other of conductor and composer has been so great over more than a century that it is impossible to consider performances of the majority of the repertoire that are not controlled by a single mind. Even if the desirability of a unifying interpreter be not accepted, it is doubtful whether a performance without a central figure who knows intimately and can control the various parts of the score would be a practical possibility. The experiment has occasionally been tried, but has resulted only in the revival of the old role of the concertmaster.

Rehearsing is one of the most important facets of the conductor's job and, certainly as far as the performers are concerned,

the one in which he is most likely to reveal his true potential. Here he naturally does not maintain silence since he must issue instructions and explain and even imitate the effect he wishes produced.

It has often been justly said that the truly great conductors have been men of wide learning and culture. Yet these qualities may not suffice to command a tough body of orchestral players unless they are accompanied by a powerful personality that arouses respect and maintains discipline. This strikes at the root of the conductor's position.

Occasionally child prodigies appear and impress orchestras and public alike with their knowledge of ability. Yet this is paradoxical since to lead a body of professional musicians in a performance of great music requires a maturity that can only be acquired through many years of learning and experience of the world. It is possible that the days of the "personality" conductor are numbered; but the position itself, complicated and influential as it is, seems indispensable.

**CONDUCTIVITY**, in heat, is the quantity of heat passing per second through a slab of unit cross-sectional area when the temperature gradient between the two faces is unity (see **HEAT**: *Conduction of Heat in Solids*; *Conduction in Gases and Liquids*). Electrical conductivity is the current or the quantity of electricity passing per second through a similar slab when the potential gradient is unity, and it is the reciprocal of the resistivity (see **ELECTRICITY**, **CONDUCTION OF**: *Conduction in Solids*).

In sound the conductivity of the orifice or neck of a resonator is the ratio of the area to the length of the orifice (see **SOUND**). See also references under "Conductivity" in the Index.

**CONDUCTUS**, a term employed in the 12th and 13th centuries for a musical setting of a Latin metrical poem for one, two or three voices. It is applied (in the form *conductum* in the *Codex Calixtinus*, c. 1130) to pieces that accompanied the reader of a lesson as he walked to the lectern; and in liturgical plays at Sens (*Conductus ad tabulam* for the Carnival of the Ass) and Beauvais (e.g., *Conductus Danielis venientis ad Regem*), to pieces accompanying processions. In church use the term was soon transferred to the tropes of and substitutes for the *Benedicamus Domino* at the end of the offices, a genre of composition that flourished in the Notre Dame school of the late 12th and early 13th centuries.

Unlike the medieval motet, which arose about 1225, the polyphonic conductus was an original composition not based on a pre-existing tenor and was composed with uniform rhythm in the parts, all of which sang the same text.

(F. L. HA.)

**CONDUIT**: see **AQUEDUCT**; **CABLE**, **ELECTRIC**.

**CONE**, in botany, the reproductive structure, also called strobilus, characteristic of the pines and other conifers and the club mosses and horsetails. See **CONIFERS**; **LYCOPodium**; **SPHENOPSIDA**.

**CONE**, in its earliest geometric use, denoted the solid space swept over by a right triangle rotating about one side (altitude or axis,  $a$ ), the other side (base,  $r$ ) tracing out the circular base of the cone, and the hypotenuse (slant height,  $s$ ) its curved surface, the vertex  $V$  of triangle and cone being the same (fig. 1).

**Cones and Conics.**—At first the size of the vertical angle of such a right-circular cone (twice that of the triangle) appeared important, and hence such cones were divided into three classes according to shape,

and were named "acute-, right-, obtuse-angled." The natural position of a plane cutting through a cone seemed to be perpendicular to the slant height (i.e., the hypotenuse or generatrix in any position, called also an element,  $e$ , of the surface). It is said that Menaechmus (c. 350 B.C.), in striving to construct the so-called double mean proportional,  $a:x = x:y = y:b$ , differentiated between three corresponding types of conic sections, afterward named, respectively, ellipse, parabola and hyperbola. It was the "great geometer," Apollonius, born at Perga in Pamphylia (c. 225 B.C.), student in the Euclid school of Alexandria, who perceived and showed that the type of cone was indifferent. Apollonius proved that any plane section of any circular cone, parallel to an element, yielded a parabola, and that other sections yielded either an ellipse or hyperbola.

**Volume and Area.**—The conception of a cone as a solid called for the measurement of its volume, a fact enunciated first by the philosopher Democritus (5th–4th century B.C.), proved by Eudoxus of Cnidus (c. 400–c. 347 B.C.), and later completed by Archimedes (287–212 B.C.), who showed that a cone, hemisphere and cylinder, all of the same base and height (fig. 2) have volumes

respectively as 1, 2, 3—a relation holding for any type of cone and cylinder. If they have equal bases and heights, the volume of the cone is one-third that of the cylinder, which is the product of base and height. It is clear that the curved surface of a right-circular cone may be thought of as being slit all along any element and then flattened out on a plane (tangent along the opposite element) into a circular sector;

FIG. 2.—RELATION OF CONE, CYLINDER AND HEMISPHERE

hence the curved surface equals in area the sector area; i.e. the half-product of base-circumference as arc and slant height as radius.

**Equation.**—In analytic geometry the equation of the right-circular cone traced by rotating the line  $y = mx$  around the  $y$  axis is  $y^2 = m^2(x^2 + z^2)$ . This simply means that, as any point  $P$  (of the line) rotates around the  $y$  axis, its  $y$ -coordinate remains unchanged, as does its distance  $\sqrt{x^2 + z^2}$  from the  $y$  axis, and the fixed ratio of these two lengths is  $m$ .

**Oblique Cone.**—The circular cone was defined by Apollonius more generally as the surface (or its enclosed volume) traced by a right line passing through a fixed point (vertex) and gliding along a fixed circle. The perpendicular line through this vertex and the centre of this circle is the axis; if this axis is at right angles to the base (the plane of the circle), the cone is right; otherwise, it is oblique, in which case the vertical angle is not of constant size. Any plane containing the axis cuts the solid in such a vertical angle, and the surface in its sides (elements of the cone). The plane that contains the axis and is perpendicular to the base of the cone forms the "principal section"; any plane perpendicular to it and inclined equally but inversely (with the base) to the generator-elements is called a "subcontrary section." This section cuts the cone in a circle, as do all planes parallel to it or to the base; all such planes are called "cyclic planes" (fig. 3).

**The Cone as a Surface.**—It was natural to regard and define the solid first rather than the bounding curved surface, and hence the early Greek achievements were largely in stereometry. It was only very gradually that it came to be felt that the surface alone possessed peculiar properties, the enclosed space being indifferent. There resulted a change in definition and treatment from three to two dimensions. From this new point of view the cone concept underwent a broad generalization, the term now designating any path of (or surface traced by) a straight line (the generatrix) that passes always through a fixed point  $V$ . This path, to be definite, is directed by some curve (the directrix,  $D$ ), along which the line always glides (fig. 4). Thus, in the right-circular cone

FIG. 3.—CYCLIC PLANES

FIG. 1.—RIGHT-CIRCULAR CONE AND ITS ELEMENTS

fig. 1, D is the circle bounding the cone's base, the track of the moving end of the hypotenuse ( $s$ ). In the oblique circular cone, D is still a circle, but is no longer traced by one certain point of the line  $g$ . If D is a conic (e.g., an ellipse) the surface is called a "quadric cone." If a fixed direction (or line called the axis) is assumed as passing through the fixed vertex V, the motion of the tracing line  $g$  might be directed by ordered variation in the vertical angle  $\alpha$  between the fixed and the moving line.

FIG. 4.—CONE AS A SURFACE DESCRIPTION

In the most important case, the right-circular cone, this variation is the simplest possible: the vertical angle is constant; the two lines are rigidly joined at V; and the generatrix swings freely around the axis (which may be thought of as turning in itself).

**Tangency.**—Such seems to be the simplest and most vivid conception of the right-circular cone; the two halves meeting at V and extending oppositely without end are called nappes or sheets. If slit throughout along an element, and rolled out (developed) on the plane tangent along the opposite element, the nappes would appear as centrally symmetric sectors of an infinite circle about V as centre. Any plane tangent to a cone passes through V and touches the cone along some element throughout. All such planes would touch the whole cone surface and would envelop it completely. The tangent plane at any given point of the surface (except V) is quite definite, but at V this definiteness disappears. All tangent planes pass alike through V.

**Intersection.**—The phenomenon of the intersection of a cone with other surfaces belongs to constructive geometry, where it is developed and applied. Its importance may be presumed from the fact that central projection is conelike, the lines of projection issuing like rays of light from a point, the vertex of the cone. An interesting special case is the spheroconic, the intersection of any quadric cone with a sphere about the vertex of the cone as centre.

**Truncation.**—In measurement, the word frustum (fig. 5) is encountered, especially in connection with the right-circular cone. Frustum, meaning piece, denotes a truncated cone, or the portion of a cone (viewed as a solid) between the base and a cutting plane generally parallel thereto. The problem of computation was apparently first proposed with respect to truncated pyramids, in Egypt. Indeed, one of the earliest extant computations of volume is Egyptian and relates to such a figure. Much later, in the *Stereometrica* of the encyclopaedic Hero of Alexandria (c. A.D. 50? or as late as A.D. 200?), the volume is calculated for a pyramid frustum on a square base (100), with the top section a square (4) and the oblique edge 9; the height is found to be 7, which, when

multiplied by  $\left[\left(\frac{10+2}{2}\right)^2 + \frac{1}{3}\left(\frac{10-2}{2}\right)^2\right]$ , gives 289½. This

is a correct result as may be seen by the now well-known rule or formula, viz., one-third the product of height by the sum of the bases and their geometric mean. But in a second example the sides of the square (base and top) are given as 28 and 4, and the slant edge as 15, which is impossible, since even the projection of any such slant on the base plane would be  $\sqrt{12^2 + 12^2}$  or  $\sqrt{288}$ , which is more than 15 =  $\sqrt{225}$ . Accordingly, the reckoner, in applying his method, of which the foregoing rule is the resultant formula, meets with  $\sqrt{-63}$ , which he treats as  $\sqrt{63}$ . Whether or not this is the work of Hero, it is notable as the oldest-known appearance of the so-called "imaginary," the square root of a negative number. The rule or formula used above holds for all

FIG. 5.—SURFACE OF A FRUSTUM

such frustums of cones and pyramids. It was used much later by the leading Hindu mathematician Brahmagupta (c. 628) in his *Brahma-sphuta-siddhanta*. The surface area of such a frustum is plainly the difference between the areas of two circular sectors (AVB and FVR) of the same angle and centre, into which the cone and the top could be rolled out on a tangent

plane (fig. 5). Hero recommends similar practical methods for measuring other surfaces, such as wrapping the solid in a thin cover and then spreading this out.

If the vertex of the right-circular cone retires indefinitely along the axis, the cone passes over into a cylinder (q.v.) or cylindric surface, and the frustum becomes an ordinary (right-circular) cylinder, its volume the product of base and altitude, and its curved surface area the product of the circle of the base by the altitude. This limiting case of the cone frustum is of course much simpler than the general case. See also ANALYTIC GEOMETRY; CONIC SECTION; SURFACES. (W. B. SM.)

**CONEFLOWER**, the popular name given in North America to species of *Rudbeckia* and other closely related genera of the family Compositae, many of which are cultivated as ornamentals. The large, solitary flower heads, often four inches or more across, consist of a cone-shaped central portion of disk florets surrounded by numerous brightly coloured ray florets. A striking example is the purple coneflower (*Echinacea purpurea*), called also red sunflower and black sampson, native to the central United States. It is a coarse, stout perennial herb, two feet to five feet high, bearing lance-shaped leaves and long leafless flower stalks each ending in a single head, sometimes five inches across, with a purplish centre and purple or crimson rays. *Rudbeckia californica* of the western U.S. is a rough-hairy, unbranched perennial, its solitary, yellow flower heads nearly five inches across. Cultivated species are easily grown in any garden soil in full sunlight. See BLACK-EYED SUSAN; GOLDEN GLOW. (N. TR.)

JOHN H. DEWARD  
PURPLE CONEFLOWER (ECHINACEA PURPUREA)

**CONEGLIANO**, a town in the Treviso province of the Veneto region, Italy, is near the Piave river, 26 km. (16 mi.) N. of Treviso by road. Pop. (1961) 22,935 (commune). Conegliano is situated on a hillside and dominated by a large castle; there is much new building along the old perimeter of the town. It was the birthplace of the painter Giovanni Battista Cima; a fine altarpiece by him is in the cathedral (1493). A railway runs to Treviso, Vittorio Veneto and Udine. The town is noted for its wines and for its Venetian cooking and a national school of viticulture is located there. In World War I Conegliano was in Austrian hands from Nov. 1917 to Oct. 1918.

**CONESTOGA**, an extinct tribe of North American Indians of Iroquoian stock. Their country was Pennsylvania and Maryland on the lower Susquehanna river and at the head of Chesapeake bay. They were sometimes known as the Susquehanna. See also IROQUOIS.

**CONEY ISLAND**, a popular seaside resort in the southern part of the borough of Brooklyn, New York city. It was formerly an island separated from the mainland by Gravesend bay, Sheepshead bay, Coney Island creek and a broad stretch of salt marshes much of which has been filled in, so that the area is actually no longer an island. Coney Island, about 5 mi. in length and from ¼ mi. to 1 mi. in width, is the westernmost of a chain of outlying sandbars that extend along the southern shore of Long Island for about 100 mi. It can be reached by subway, parkways and boat.

Coney Island is one of the best known amusement resorts in the U.S. and frequently during the hot summer days over 1,000,000 people jam its sandy beaches and amusement parks. The bathing beaches stretch for 2½ mi. and are bordered by an 80-ft.-wide boardwalk. To accommodate the huge crowds large parking areas and municipally owned bathing facilities have been constructed. Several amusement centres have been developed with carousels, exhibitions, dancing, concerts, freak shows, roller coasters, penny arcades, assorted game booths, Ferris wheels, shooting galleries,

souvenir shops and hundreds of eating places.

Coney Island is also a popular all-year residential community. At the extreme western end is the district known as Sea Gate, an exclusive residential section which became an all-year community with the natural influx of summer residents. A \$123,000,000 housing project occupies the site of Luna park. In 1956 the Brooklyn Public library opened a new branch on Mermaid avenue. An aquarium, under the administration of the New York Zoological society, was built at Coney Island in the late 1950s. (D. L. D.)

**CONFECTIONERY MANUFACTURE.** For centuries man has devoted time and effort to perfecting the skills of confectionery manufacture, the art of properly blending various agricultural products into an attractive, palatable food known as candy. Written and pictorial records of candy were left by the Egyptians and from these it is learned that early candymakers used honey as a sweetener, sugar being unknown, and added figs, dates, nuts and spices. The sweets were shaped in rough, crudely shaped molds and were highly coloured to attract attention.

There is little reference to the manufacturing of candy until about the middle of the 14th century, when sugar shipped into Venice was used for making confections. It was not until the cultivation of sugar cane spread throughout the world and the refining of sugar was developed that the confectionery industry began to grow. Prior to this time, a confection was an item sold or dispensed only by pharmacists and spice stores. By the 16th century confectioners were making many kinds of sweetmeats and candy by molding sugar, nuts and fruits of various kinds into fanciful forms. In those days, only hand methods were employed. The few utensils and appliances used were primitive and crude. They were used principally in cooking or boiling the sugar and molding or shaping the candies. Not until the latter part of the 18th century was there any notable development in the invention of candy machinery. The 20th century saw the development of confectionery manufacture to a world-wide annual production totaling thousands of millions of pounds.

**Candy Ingredients.**—More than 77 agricultural products are used in making candy; they include sugar, corn products, chocolate, eggs, fruits, nuts, butter, milk and cream. The main ingredients used for manufacturing candy are cane and beet sugars combined with other carbohydrate foods such as corn sirup, corn sugar, cornstarch, honey, molasses and maple sugar. To the sweet base are added chocolate, fruits, nuts and peanuts, eggs, milk products, flavours and colours. In food value, candy is a concentrated source of food energy; milk, fruits and nuts, where used, supply additional nutritive value.

**Classifications of Candy.**—There are more than 2,000 different kinds of candy, but these all fall into a few general classes.

**Hard Candy.**—The simplest forms of candy are the hard candies, made mainly from sugar and corn sirup and characterized by their hard brittle texture. The ingredients are cooked to a practically moisture-free candy sirup, which is flavoured, coloured and formed into various shapes. Typical hard candies are lemon drops and the various intricately designed solid and filled Christmas candies. After-dinner mints, peanut brittle and taffy are considered hard candies.

**Lozenges.**—Lozenges and pressed tablets are made from powdered sugar with flavours, colours, natural gums and gelatin added. These ingredients are kneaded into a dough that is compressed and stamped by machine.

**Caramel and Toffee.**—Caramels depend on large amounts of milk for their typical texture. The other ingredients are sugar, corn sirup and fat, which are cooked until the desired degrees of caramelization and texture have been attained. The most popular flavours are vanilla and chocolate. Toffee is highly cooked or hard caramel.

**Cream or Fondant Candies and Fudges.**—Cream or fondant candies are made by kneading the cooled mass of a highly cooked sirup that consists principally of sugar with a small amount of corn sirup. Fruits, nuts, flavours and colours are added to make the variety of creams found in boxed chocolates. When the fondant cream has been prepared, it is extruded through a die and cut to the desired size, or it is molded in starch by the following

process: trays are filled with food starch, then imprinted with molds of whatever shape is desired. Fondant cream is deposited in the imprints and allowed to set. When set, the centres are taken from the trays and cleaned of any starch that might adhere. They are then ready for dipping, crystallizing or glazing. Candy corn seen during the Halloween season is typical of the glazed hard cream or fondant candy. Another variety is the French cream, which has a sugar-crystal jacket formed by immersing the fondant centre in a saturated sugar solution.

**Fudge,** which contains milk, cream and edible fats in addition to sugar and corn sirup, is characterized by its smooth creamy texture. Flavours, colours, nuts, peanuts, fruit and chocolate are added to give variety.

**Candy Jellies or Gums.**—Candy jellies or gums are made with sugar, corn sirup and a jellying agent such as starch, pectin, natural gums or gelatin. They are characterized by their jellylike consistency, varying from a soft and tender to a hard gummy texture. Candy orange slices or soft gumdrops are typical of the soft-textured starch jelly, while the familiar jujube is an example of the hard-textured gum.

**Marshmallows.**—This familiar confection is made by whipping a combination of sugar, corn sirup, gelatin or egg whites or both, and flavours. It is characterized by its light, fluffy texture. The soft tender form is the popular sugar-dusted, white marshmallow and the grained types are the circus peanuts, marshmallow bananas and the panned marshmallow eggs seen at Eastertime. Marshmallow candies are cast in starch in the same way as creams or some varieties are extruded and cut to size.

**Nougats.**—Nougats are aerated chewy candies made by adding a highly cooked candy sirup (made with sugar and corn sirup) to a frappé or whip, which is formed by whipping a solution of egg whites or gelatin or both. Vegetable fats are added to impart chewiness, and variety is given by adding fruits, nuts, honey and the like.

**Licorice.**—Licorice candies are made with flour, molasses, sugar and corn sirup and flavoured with licorice extract.

**Chocolate.**—The common chocolate coatings are bittersweet chocolate, sweet chocolate, milk chocolate, skim milk and butter-milk chocolate and imitation chocolate (summer coatings). These chocolates are used for coating other candies and also for manufacturing bars, plain chocolate and with a mixture of peanuts and other nut meats. Coatings are made by grinding roasted cocoa beans with sugars, cocoa butter, dried powdered-milk products and flavours to give the smooth texture associated with chocolates. (See COCOA: *Manufacture and Uses*.)

**Coated Candies.**—Coated candies are usually a combination of one of the above basic candies and a special coating of chocolate, fondant, icing, coconut or nuts. Packaged chocolates are composed of a variety of types of chocolate-coated candies.

Coated candies that have a hard, glossy jacket are called panned candies and may be either sugar-coated or chocolate-coated. Sugar-coated panned candies, which are typified by jelly beans, Jordan almonds and French burnt peanuts, are produced by placing centres and a specific amount of sugar sirup in huge revolving pans similar in shape to barrels. Coating and polishing are accomplished by the continuous revolving action of the pans. Chocolate-panned caramels, nuts and peanuts, raisins and malted milk balls are coated in the same manner by substituting a chocolate coating for the sugar sirup.

**Candy Bars.**—Because of their tremendous popularity, candy bars require a separate classification and can be defined as individually wrapped candies usually selling in the U.S. for five and ten cents. The three most popular types are (1) plain chocolate with or without nuts; (2) chocolate-coated simple and compound centres such as nut rolls (fudge centre rolled in caramel and nuts then chocolate-coated), nougat-caramel combination and hard candy-peanut butter combination and (3) nonchocolate-coated (solid nut bars, caramel, toffee, fudges, etc.). The possible combinations for candy bars are practically endless.

**Specialties.**—These, some classifiable under headings given above, are of interest though representing a small percentage of candy manufactured. They include cotton candy or spun sugar

popular with children at circuses and amusement parks; "message" candies, which are lozenges pressed in heart and flower shapes with messages printed on them; candies simulating other food items, such as bacon and eggs; in the Rocky mountain area, candies simulating pebbles; pecan pralines, common particularly in the southern U.S.; and cinnamon drops or hearts, sometimes called a specialty but regarded by some as a standard household item for decorating cakes and flavouring baked apples.

(See also CHEWING GUM.)

**The Industry in the U.S.**—The U.S. department of commerce, with financial support from the National Confectioners association, publishes an annual report entitled "Confectionery Sales and Distribution" that gives statistics covering more than 90% of the industry excluding chewing gum. By the end of the 1950s this report showed annual sales values (at the manufacturers' level) of \$1,150,000,000, the highest recorded up to that time. Per capita consumption in the U.S. reached a high of 20.5 lb. during 1944 as a result of government purchases for military rations and resale. Consumption fell to a low of 15.5 lb. in 1955 and rose continuously to 16.8 lb. at the start of the 1960s. The mass producers of candy (manufacturers-wholesalers) are concentrated in five states. On a weight basis Illinois produced 39.3%, New York and New Jersey 17.7%, Pennsylvania 8.9% and California 4.8%, for a total of 70.7%. Types of candy produced on a quantity basis were chocolate-coated bars 14.8%, other bars 17.1%, other five- and ten-cent specialties 9.6%, package goods retailing above 50 cents per pound 13.4%, less than 50 cents per pound 23.1% and bulk goods 21.0%.

**Sales Outlets.**—Confectionery manufacturers in the early 1960s made their products available to the consumer in more retail outlets than did producers of any other food. Confectionery was available through vending machines located in many convenient places including industrial plants, newsstands, and in several hundred thousand food stores, department stores and candy stores. An estimated 20% to 30% of sales was through grocery stores.

For information about homemade candies see FOOD PREPARATION: Confections.

**CONFEDERATE STATES OF AMERICA**, the name of the independent government formed by the southern states that seceded from the Union in 1860 and the early part of 1861. (See also AMERICAN CIVIL WAR; SOUTH, THE; UNITED STATES [OF AMERICA]: History.) For a quarter of a century before 1860 there had been developing a steadily increasing bitterness between the northern and southern sections of the United States, growing out of economic, social and political differences; and out of these differences there had arisen a disagreement on the meaning of important parts of the federal constitution. The South was largely an agricultural region producing cotton, sugar and tobacco; the North, though also an agricultural section, had developed more along industrial and commercial lines than had the South. From the settlement of the colonies, slavery had been an important factor in the development of agriculture in the South and with the increase of the Negro population it had come to be looked upon by slaveholders as well as nonslaveholders as a method of solving the race problem. After the American Revolution, the North gave up slavery as uneconomical, and by the 1830s a movement had sprung up there to abolish slavery in the South. (See ABOLITION MOVEMENT.) This opposition to slavery lay at the bottom of the sectional bitterness. The protective tariff also entered into the disputes, for it aided northern industries, increased the prices paid by southerners for goods they purchased and yet gave no protection to the South's agricultural products. As a move toward suppressing slavery, the North sought to prevent its spread into the territories, while the South declared it had a constitutional right to take its slaves there.

**Secession.**—The sectional dispute came to head in 1860 when

Abraham Lincoln was elected president. The southern states held that both Lincoln and the Republican party threatened their constitutional rights in the Union, their social institutions and way of life and their economic existence. For a decade and more, important southern leaders had argued that secession might be their only protection; and the time for it seemed to be at hand. South Carolina began the process by withdrawing from the Union on Dec. 20, 1860. The movement quickly spread to Georgia and the states bordering on the Gulf of Mexico, and before the end of Jan. 1861 all had seceded except Texas, which withdrew on Feb. 1. The other slave states in the upper South and on the border were greatly agitated but they hesitated to secede for the time. But when on April 12, 1861, the southerners fired on Ft. Sumter, in Charleston harbour, and when war seemed evident by President Lincoln's call on the states then in the Union for troops to enforce the laws of the land, another wave of secession was set going. During April and May all of the states of the upper South withdrew, Virginia (April 17), Arkansas (May 6), Tennessee (May 7) and North Carolina (May 20). The border slave states became greatly excited, and there were strong secession movements in Maryland, Kentucky and Missouri. In Kentucky a meeting of delegates declared that state out of the Union, and in Missouri a fragment of the legislature passed a secession ordinance. The Confederacy admitted Kentucky and Missouri as states to make up the magical 13, but the action of both states was irregular. The other 11 states that composed the Confederacy had all been carried out of the Union by conventions elected by the people, except Tennessee, where the full legislature acted. And all except Tennessee had asserted their constitutional right to secede; Tennessee based its withdrawal on the right of revolution.

**Confederate States Government Organized.**—For many years some southerners had dreamed of a southern nation, and with six states in secession, they decided to bind these states into a new nation. It was necessary to make haste without waiting for the upper South to follow, for Abraham Lincoln would be inaugurated on March 4, 1861, and it was feared that he might take stern action immediately. So it was arranged for delegates from these six states (to be joined later by those from Texas) to meet in Montgomery, Ala., on Feb. 4. This convention, presided over by Howell Cobb of Georgia, immediately began to frame a document setting up the new government. Four days later it adopted unanimously the provisional constitution of the Confederate States of America, which was to serve until a permanent constitution could be written. This document was rudimentary, and its chief purpose was to provide the framework of a central government. It called for a president and a vice-president to be elected by the states (each state having one vote); a supreme court composed of the district judges; a congress of one house (the existing convention to continue as that body); the capital to be at Montgomery until congress should change it; and the government thus established to continue for only one year. The leaders were anxious that there should appear to be no factions in this convention. After various conferences they chose Jefferson Davis (q.v.) of Mississippi for president and Alexander H. Stephens (q.v.) of Georgia for vice-president. Davis, who was not a member of the convention and who had no desire for the presidency, set out immediately from his Mississippi home and was inaugurated on Feb. 18, after a grand procession with a band playing "Dixie" marched up the hill to the Alabama state capitol.

In selecting his cabinet, President Davis was careful to see that all of the seven states (except Mississippi, which held the presidency) were recognized. Christopher G. Memminger of South Carolina became secretary of the treasury; Robert Toombs of Georgia, secretary of state; Stephen R. Mallory of Florida, secretary of the navy; Leroy P. Walker of Alabama, secretary of war; Judah P. Benjamin of Louisiana, attorney general; and John H. Reagan of Texas, postmaster general. During the four years of the Confederacy, there were various changes in the personnel of the cabinet; but three served throughout the whole period. Benjamin, one of the ablest men in the Confederacy, was first transferred to the war department and finally to the state department; Mallory, who was bitterly criticized during the war and for

years afterward but came to be recognized as an able administrator, continued in the navy department; and Reagan, a staunch supporter of Davis, administered the post office throughout the war. President Davis was probably the best selection the Confederates could have made, despite the fact that he was ill much of the time, had the use of only one eye, and seemed to lack that warmth of character and approach which would have made him much more popular. Stephens was soon to become an outspoken critic of Davis and of many Confederate policies.

The convention, which was the congress under the provisional constitution, when not busy providing for the needs of the new government, turned its attention to framing the permanent constitution. On March 11 its work was completed when it adopted the document by a unanimous vote. The proposed constitution was then submitted to the states that had seceded and all of them ratified it. This constitution throughout its framework was a modified copy of the constitution of the United States, for the southerners had time and again insisted that they had no quarrel with that document. Their objection was to the way the North was interpreting it. But there were important additions and clarifications that made it one of the most interesting documents in U.S. history. The president was to serve for a term of six years and be ineligible for re-election; the president might veto separate items in appropriation bills; with the consent of congress, cabinet members might have seats on the floor of either house; a budget system was adopted, and congress was not authorized to increase items in a budget except by a two-thirds majority; after the first two years the post office department was required to be self-sustaining; the foreign slave trade was prohibited; and no law could relate to more than one subject. By way of clarification, congress was forbidden to foster any industry by a protective tariff, appropriate money for internal improvements or limit the right to take slaves into a territory. Although there was a provision for a supreme court, congress never set one up, largely through fear of the power it might assume, reminiscent of the record of the U.S. supreme court.

The love of the old Union was reflected not only in copying the federal constitution but also in the search for a flag. The congressional committee appointed to design a flag received many suggestions for a modification of the Stars and Stripes and even to take over the flag itself. The result was the Stars and Bars, which continued the red, white and blue colours but had only three stripes; the field was blue with 7 white stars. However, this was enough to confuse it with the United States flag. Confederate troops at the first battle of Bull Run had difficulty, in the heat and dust of battle, in distinguishing their own reinforcements from those of the enemy. To prevent a repetition of this a new banner, the Battle Flag was designed, its red field crossed diagonally by a blue cross with 13 white stars. Despite its wide use, however, this famous flag was never officially adopted. In May 1863 the Confederate congress adopted a second national flag, known as the Stainless Banner. It was pure white with the Battle Flag in the left corner. Because this flag, when hanging limp, looked too much like a flag of truce, the Confederate congress on March 4, 1865, changed it by placing a broad red bar across its end. This was the last flag of the Confederacy. (For the succession of flags, see illustration.) (See also FLAG.)

For the designs on its stamps the post office department selected national heroes, such as Jefferson, Jackson and Calhoun, but not Washington, whose portrait was at that time on a United States stamp. Very soon the Confederacy began a system that was unique in American history: it used the picture of a living person on its stamps—Pres. Jefferson Davis. The letter rate soon came to be ten cents per ounce—twice the rate in the North.

In Nov. 1861, as provided by the permanent constitution, elections for president, vice-president and members of congress were held throughout the Confederacy. Davis and Stephens, who had been serving provisionally up to this time, were elected to full six-year terms, and a congress of two houses was chosen for the first time. In the meantime the convention had changed the capital city from Montgomery to Richmond, Va., and the government had moved there during the summer. The second inaugura-

tion took place in the Virginia capital on Feb. 22, 1862, on a bleak, cold, rainy day—a sombre occasion as the president looked out on a sea of black umbrellas and read his address. It was a great contrast to the balmy day in Alabama when he was first inaugurated. Already the superstitious were thinking that here was a harbinger of dark days ahead.

**Ft. Sumter.**—On assuming office President Lincoln had declared that states could not secede, that the Confederate states were not actually out of the Union and that he would enforce the laws everywhere. His first problem was to hold the forts in the Confederacy which that new government had not already seized. Ft. Sumter was the most troublesome and the most explosive, for the Confederacy held that it was unthinkable that one of its forts should be occupied by a foreign country. It immediately attempted to open negotiations in Washington but President Lincoln would not receive the Confederate emissaries. The Confederate military forces fired on the fort and after suffering a bombardment of more than a day it surrendered on April 13. This was war and both parties began to make preparations to carry it on effectively.

**Raising Troops.**—Immediately after its organization the Confederacy had made preparations to raise, organize and equip an army, although it hoped (and many of its leaders believed) that it would not have to fight to maintain its independence. After the fall of Ft. Sumter and Lincoln's call for troops, the Confederacy speeded up its preparations for defending itself. Originally it had expected its armies to be made up of troops offered by the states, for at that time the general feeling prevailed that the Confederacy was little more than a combination of "sovereign" states; but after Ft. Sumter, congress gave President Davis the right to accept troops through direct volunteering and fixed the number at 400,000. Great enthusiasm prevailed everywhere and soon the Confederacy had more troops than it could equip; some were even sent back home. But before the end of the year 1861 the war had exploded into far-flung battlefields, from Virginia to Missouri and along 3,500 mi. of coast line. Additional laws were passed for raising troops, but less than a year after war had begun the Confederacy found that it needed more troops than were coming forward. With the passing of a law in April 1862 that established a system of conscription (*q.v.*), the Confederacy embarked on a policy which the United States government had not yet attempted. All male citizens between the ages of 18 and 35 were declared to be in the Confederate army unless they were exempted for physical reasons or were needed in civilian capacities to provide for the armies or maintain the general welfare. There were a great many industrial exemptions as well as the exemption of teachers, preachers, hospital workers and others in similar occupations. By later legislation the age limits were extended from 17 to 50 and the number of exemptions was greatly reduced. Finally, before the end of the war, the system of exemptions was abandoned, and the president was given the task of "detailing" persons for necessary civilian work. No accurate records of the total number of Confederate soldiers survived the war but careful estimates suggest about 750,000. They fought against about twice that number of Federal troops.

Disappointed in their hopes of peaceable separation, the Confederates were prepared to defend themselves, despite their great disparity of men and resources. The 11 Confederate states had a white population of about 5,500,000. There were about 3,500,000 slaves and 130,000 free Negroes. Remaining under the federal government were about 22,000,000 people. In industrial resources, the Confederacy was far inferior to the United States. It had only about 9,000 mi. of railroads as compared with 22,000 mi. in the North. But President Davis in his two inaugural addresses in his messages to congress and in many proclamations and public addresses built up the enthusiasm of the people and steeled their hearts to win the war. The race, he asserted, was not to be swift, nor the battle to the strong; the will to win would in the long run bring victory. In his second inaugural address he said: "True to our traditions of peace and our love of justice, we sent commissioners to the United States to propose a fair and amicable settlement of all questions of public debt or property."

(A) FIRST FLAG OF THE CONFEDERATE STATES OF AMERICA, THE STARS AND BARS, MARCH 4, 1861, CONSISTING OF A HORIZONTAL WHITE BAR BETWEEN TWO RED BARS, AND A CANTON OF 7 WHITE STARS ON A BLUE FIELD. (B) BATTLE FLAG, A WHITE-BORDERED RED FIELD, USUALLY SQUARE, WITH 13 WHITE STARS ON THE DIAGONAL ARMS OF A WHITE-EDGED BLUE CROSS; (C) STAINLESS BANNER, MAY 1 1863, A PURE WHITE FIELD WITH THE BATTLE FLAG IN THE CANTON; (D) LAST FLAG, MARCH 4, 1865, THE STAINLESS BANNER WITH A BROAD RED VERTICAL BAR AT THE OUTER EDGE

which might be in dispute. But the government at Washington, denying our right to self-government, refused even to listen to any proposals for a peaceable separation. Nothing was then left to do but to prepare for war."

President Davis, who had been an officer in the Mexican War and later U.S. secretary of war, was active in dictating military policy and major strategy of the Confederacy. With a few exceptions he tenaciously clung to a policy of defense instead of taking the offensive and carrying the war into the North. Failing to give due recognition to the importance of the military frontiers across the Appalachian mountains and beyond the Mississippi river, Confederate military policy held that Richmond must be defended to the utmost and that the war would be won or lost in Virginia. Also there was a feeling among some Confederate military leaders that early in the war not enough attention was being given to the development of the cavalry, which might have been used to invade the North and bring the war to a close.

The initial strength of the Confederacy lay not only in the fighting qualities of its common soldiers, who had the feeling that they were defending their homes from the despoilers, but also in the ability of its officers, many of whom had resigned from the U.S. army to join the Confederacy. There was a tower of strength in Robert E. Lee after he became commander of the army of northern Virginia in 1862. Thomas J. ("Stonewall") Jackson was his most able lieutenant until his death the next year at the battle of Chancellorsville. James Ewell Brown ("Jeb") Stuart, mortally wounded at Yellow Tavern in 1864, was a cavalry leader par excellence. Nathan Bedford Forrest, as daring and resourceful a cavalryman as fought in the war, was discovered too late to greatly affect Confederate prospects of ultimate victory. Albert Sidney Johnston, killed early in the war at Shiloh, did not live long enough to contribute much of his ability as an outstanding soldier. Joseph E. Johnston and Pierre G. T. Beauregard were able leaders but wasted some of their time and enthusiasm in disagreements with President Davis.

Losses of Confederate soldiers resulted not only from their deaths on the battlefield and in hospitals but also from desertion and capture. A system for exchanging prisoners of war was soon abandoned because of disagreement between Confederate and Federal commissioners, and it became the task of each belligerent to set up prison camps. The principal camps in the North were Elmira, Camp Chase, Johnson's Island, Camp Douglas, Point Lookout, Delaware and Rock Island. The Confederates, much less able to take care of prisoners, established camps at Richmond (Libby and Belle Island); Salisbury, N.C.; Florence and Columbia, S.C.; Millen, Macon and Andersonville, Ga.; and at other places. Andersonville became notorious for the large number of deaths that took place there. The Confederate government sought frequently but unsuccessfully to reinstitute an exchange of prisoners, and offered to accept and administer any medical aid that the federal government might give; but this offer was rejected. The Confederacy cited these facts and also the large number of Confederate deaths in northern prisons in defending itself against northern charges of barbarous conditions in southern prisons.

**Financial Affairs.**—The Confederacy began its existence with an empty treasury. To tide it over its first few days, the state of Alabama loaned it \$500,000. It soon seized a few hundred thousand dollars in the customhouses and almost \$400,000 in the New Orleans mint. But the Confederacy needed to set up a system to provide steady income. At first, thinking that there would be no war or at most a short one, the Confederate government resorted to printing money and issuing bonds. This method was less painful, more popular and even more logical than taxation, for it was argued that if a complicated system of wartime taxation were set up it might have to be abandoned very soon. An act of March 9, 1861, provided for the issuance of not more than \$1,000,000 of paper money in denominations of not less than \$50. This act was soon followed by other laws providing for smaller denominations and in amounts that reached almost astronomical proportions. Throughout the war about \$1,500,000,000 was issued; and although at times the amount in circulation was somewhat reduced by being absorbed in payment for bonds, still Secretary Memminger (against whose recommendations this money was being printed) could say at various times that the amount in circulation was five times beyond the country's needs. As the currency increased, prices became fantastic. Near the end of the war a soldier could not have bought a pair of shoes with all the pay he would have received if he had enlisted at the firing on Ft. Sumter and had remained continuously in the service thereafter. At the end of the war a soldier wrote an apostrophe to a Confederate note on the back of one, in four stanzas, of which this is the first:

Representing nothing on God's earth now,  
And naught in the waters below it,  
As the pledge of a nation that passed away,  
Keep it, dear friend, and show it.  
Show it to those who will lend an ear  
To the tale this paper will tell,  
Of liberty born of a patriot's dream,  
Of a storm-cradled nation that fell.

The Confederacy's record of bond issues was as reckless as its orgy in printing notes. Its first bond issue was provided for in an act of Feb. 28, 1861, that allowed the president to borrow not more than \$15,000,000 at 8%. With the beginning of fighting the floodgates for bond issues were opened and through the passing of successive acts more than \$700,000,000 of bonds were issued. To speed the marketing of bonds congress passed laws in May and August 1861 providing that bonds might be paid for to the amount of \$100,000,000, in military supplies, manufactured articles and in agricultural products. This was commonly known as the cotton loan, since that product was generally used in paying for these bonds. Also, other issues of bonds were paid for in cotton, so that in the course of time the Confederate government came to possess almost 500,000 bales. With this cotton on hand, the Confederacy used some of it as a guarantee for the payment of a loan which it secured in Europe through the banking firm of Erlanger and Company of France. The bonds were to be issued to the amount of 70,000,000 fr. They bore 7% interest and were due in 20 years. As the cotton remained in the Confederacy, those who

bought the bonds lost their money but from the loan the Confederacy obtained about \$2,600,000.

An export tax on cotton of  $\frac{1}{2}$  cent per pound was provided in Feb. 1861, and a so-called war tax of one-half of 1% on the taxable wealth of the Confederacy was levied in the following August. Both taxes were collected only once. Apart from these two taxes, the Confederacy tried to finance itself without any internal taxation at all for the first two years of its existence. In April, May and August 1861 laws were passed levying tariff duties on a long list of items; but since the blockade of southern ports greatly restricted commerce with other nations, the tariff throughout the life of the Confederacy brought in little more than \$1,000,000 computed in specie. This was a tariff for revenue—not a protective tariff, which was forbidden by the Confederate constitution. Not until April 1863 did congress finally pass a general tax bill, later amended and made more inclusive. A large number of licence and occupational taxes were levied against banks, bowling alleys, liquor stores, hotels and so on. Taxes were also levied on the sales of certain articles. There was an income tax ranging from 1% through 15%. A profits tax was also included, designed to work against speculators. The products of agriculture were not included in this law, except to be taxed only once. Thereafter there was to be a tax provided in another law, reminiscent of tithing in biblical times, that levied a 10% tax on farm products, to be collected in kind. There was much opposition to this tax, for it was difficult to enforce against those living in out-of-the-way places.

In supplying the sinews of war, the Confederacy resorted to almost every conceivable device. The United States had instituted a blockade of southern ports in April 1861; but the Confederate blockade-runners were able to get through frequently during the first two years, and to some extent until Feb. 1865, when Wilmington, N.C., the last of the blockade-running ports, was finally captured. Large profits were made by private blockade-runners until 1864 when the Confederate government put all blockade-running under strict supervision. After that time fewer luxuries and more war necessities were brought in. Frantic efforts were made to set up iron foundries, armouries, arsenals and factories for the manufacture of cloth and the many other articles for which southerners before the war had depended on the North. They devised a long list of substitutes for the many drugs and medicines from which they were now cut off. To checkmate the horde of speculators who dealt in almost every necessary article, the Confederate government set up a system of impressment of farm products (in addition to the tax in kind) whereby the prices of food and feed for the armies were fixed periodically. Often these prices were about half the market price that civilians were forced to pay.

**Foreign Affairs.**—One of the reasons why southerners were so confident before secession and in the early days of the Confederacy that they could succeed in setting up an independent government was the power they believed rested in cotton—King Cotton, as they had long been calling it. As more than half of the value of U.S. exports had been in cotton, southerners felt that by withholding it permanently they could force the United States to recognize southern independence. They also believed that by withholding it from England and France they could force these countries to recognize the independence of the Confederacy. Immediately on the organization of the Confederate States government, President Davis sent a mission to Europe to ask for recognition of Confederate independence and to induce England and France to break the blockade by sending ships for cotton and thereby involve them in the war against the United States. William L. Yancey was the principal one of these three commissioners. They visited England, France, Belgium and the pope in Rome; but nowhere did they receive recognition of Confederate independence or a promise to break the blockade, though a later commissioner offered France a large bribe in cotton to do so. After a futile few months in Europe, Yancey returned with the advice that the Confederacy would have to win its independence on the battlefields. Before the end of 1861, two additional commissioners were sent, James M. Mason and John Slidell. On the way across

the Atlantic, a United States warship removed them from the "Trent," a British merchantman, and nearly precipitated a war with England. Mason and Slidell were allowed to proceed to Europe, where for the remainder of the war they sought to gain recognition of southern independence. They and other Confederate agents, chief of whom was James D. Bulloch, succeeded in buying a great deal of war material and obtaining several fast ships that were fitted out as commerce raiders after delivery. The best known of these were the "Alabama," the "Florida" and the "Shenandoah." Under Comdr. Raphael Semmes, the "Alabama" destroyed a vast amount of U.S. shipping on the high seas and almost led to war between the United States and England (see "ALABAMA" ARBITRATION). The Confederacy did not receive recognition of its independence from any country, although in the last few months of its existence it offered to free all its slaves if England would give that recognition.

**The Collapse of the Confederacy.**—Having entered the war to defend their independence, the Confederates held the strong conviction that they would win. Although they suffered some disasters, they were greatly heartened by their military victories during the first two years and were still sure of final success. But the third year saw the defeats at Gettysburg and Vicksburg, which occurred almost simultaneously, and from then on, the wisest southerners felt that they probably could never win on the battlefield. Yet in the summer of 1864, when Gen. Ulysses S. Grant was suffering staggering losses of men in his campaign around Richmond, there was a possibility that the North would become discouraged and make peace, and especially so if, in the presidential election in November, Gen. George B. McClellan should defeat Lincoln. But Lincoln was not defeated, and from that time on, southerners became more and more war-weary and demanded that President Davis call a conference with Lincoln to make peace. Davis knew well, as Lincoln had so often said, that the North would never make peace unless the Confederacy gave up and re-entered the Union. Finally, to silence the increasing spirit of defeatism in the Confederacy, in Feb. 1865 Davis sent a peace mission to talk to Lincoln on terms of a treaty. The meeting, held on a ship in Hampton Roads, was attended by Lincoln, Seward and others representing the North and by Alexander Stephens and others representing the South. The meeting was a complete failure. The will to win now sank lower in the South. The supply of soldiers had nearly run out so much so that the Confederacy was ready to make soldiers of its Negro slaves and desertion was increasing. On April 9, 1865, Lee surrendered a dwindling half-starved army at Appomattox, and a few weeks later all the armed resistance in other parts of the Confederacy collapsed. The war was over, and the Confederacy now became the Lost Cause.

**CONFEDERATION**, primarily any league or union of people or bodies of people. The term in modern political use is generally confined to a permanent union of sovereign states for certain common purposes; e.g., the German confederation (*Bund*), established by the congress of Vienna in 1815. The distinction between confederation and federation (see **FEDERAL GOVERNMENT**), terms synonymous in their origin, has been developed in the political terminology of the United States. Up to 1789 the U.S. was a confederation: then the word federation, or federal republic, was introduced as implying closer union. This distinction was emphasized during the Civil War between North and South, the seceding states forming a confederation (Confederate States of America) in opposition to the Federal Union. Confederation thus came to mean a union of sovereign states in which the stress is laid on the sovereign independence of each constituent body (cf. Ger. *Staatenbund*); federation implies a union of states in which the stress is laid on the supremacy of the common government (Ger. *Bundesstaat*). The distinction is, however, by no means universally observed. The variant "confederacy," derived through the Anglo-French *confederacie* and meaning generally a league or union, whether of states or individuals, was applied in America in the sense of confederation to the seceding southern states. In its political sense confederacy has generally come to mean rather a temporary league of independent states for certain purposes. As applied to individuals "confederacy" is often used to describe a secret combination, probably for illicit purposes. In trade-union terminology a federation (e.g., the Miners' Federation of Great Britain) is an alliance of autonomous unions; whereas a confederation (e.g., the Iron and Steel Trades confederation) is a body to which the constituent unions have handed over the majority of their powers; i.e., a disguised form of amalgamation, made necessary by the provisions of British law.

**CONFEDERATION, ARTICLES OF:** see **ARTICLES OF CONFEDERATION**.

**CONFERENCE**, a bringing together, for purpose of discussion and sometimes decision, of representatives of sovereign states or of delegates of all sorts of bodies and societies. In British constitutional history the Colonial conference was changed to that of Imperial conference in 1907, becoming the Commonwealth conference in 1949. The annual meetings of British political parties are also called conferences. In the United States national and state meetings of political parties are known as conventions. (See **NATIONAL CONVENTION**.)

The word is also applied to the regular assemblies for transacting church business. In this field the Lambeth conference, a decennial world meeting of archbishops and bishops of the Anglican communion, is one of the most important. In the Roman Catholic Church such an assembly is styled council and in the Orthodox Eastern Church, synod. Annual meetings of associations are described as conferences in Great Britain but generally as conventions in the United States. See also **CONFERENCE, INTERNATIONAL**; **WORLD WAR II CONFERENCES, ALLIED**.

**CONFERENCE, INTERNATIONAL**, in international relations, is a useful device of diplomacy. Originating in the 16th century (congress of Cambrai, 1529), it came into prominence with the congress of Westphalia (1645-48) and into more frequent and regular use in the 19th century with the congress of Vienna (1814-15). As a method of direct negotiation and consultation between states it was distinguished from negotiations through ordinary diplomatic channels and conferences. Congresses were defined in the Quadruple or Grand alliance (1814) as meetings "either under the immediate auspices of the sovereigns themselves, or by their respective Ministers." Thus the congresses of Aix-la-Chapelle (1818), Troppau (1820), Laibach (1821), Verona (1822), in the "congress period," and those of Paris (1856) and Berlin (1878) were indeed attended by sovereigns or their ministers. Other 19th-century meetings attended by ministers and plenipotentiaries were called conferences; these included the first Hague peace conference (1899).

The term congress was largely abandoned in the 20th century in favour of the term conference (e.g., conference of Algiers, 1906; Paris peace conference, 1919; San Francisco United Nations Conference on International Organization, 1945). However, the technical meetings of the Universal Postal union held periodically from 1863 were all called congresses. The prevailing tendency is to call all major official meetings conferences, and attempts to distinguish congresses from conferences on the ground of the rank of participants, the solemnity of the occasion or the importance of the agenda or of the results are scarcely tenable. The objective common to all of them, at whatever level, is the promotion of the orderly and peaceful coexistence of states.

The multilateral approach to the solution of major problems of general interest brought into use the phrase "diplomacy by conference." As the great powers were responsible for developing this method among themselves, the question arose as to the participation of powers of lesser rank. In 1818 at the congress of Aix-la-Chapelle, the great powers declared that meetings concerned with the interests of other European states would be held "under the express reservation of their right of direct participation therein, either directly or by their Plenipotentiaries." This principle was applied, if at all, in a manner resented by the states concerned which claimed participation on a footing of equality. From 1907 participation of lesser powers in international conferences was the rule. This may be attributed in part to the—misplaced—application of the principle of equality of states recognized in international law in the sense of equality of all states before the law, and in part to the principle that no state is bound by a treaty without its consent and that consequently it was the better part of wisdom to invite all interested states to conferences, especially those concerned with the progressive development of international law. Participation, then, is neither a right nor a duty but depends solely on convenience, power or geographic position, initiative of the inviting states or other factors, and may be unconditional or conditional regarding agenda, objectives, absence or presence of certain states.

Conferences are sometimes classified political or bargaining and nonpolitical; legislative, diplomatic and technical; and periodic and *ad hoc*. Nonpolitical conferences are subdivided into administrative, economic, humanitarian, social, communications, scientific, educational or cultural. Conferences may be called legislative if they result in the codification or development of international law, and diplomatic or technical depending on whether attended by diplomats or technical experts. Such classifications are merely of relative value as some conferences, notably peace conferences, embrace a wide range of objectives and include diplomatic along with technical representatives.

Proposals to convene a conference are subject to consultation among the states concerned as to desirability, time, place, agenda, objectives and other preliminaries. There are no fixed rules regarding the place, although conferences usually meet in the territory of the inviting state. Sometimes a place in a neutral territory or one removed from the pressure of public opinion and emotions is preferred (Locarno conference, 1925). The formal opening is usually performed by the chief delegate of the host state if that state is also a participant. Questions of precedence related to a doubtful hierarchy of states, once important, are largely obsolete.

The first item of business is the election of a permanent president and of vice-presidents, who together with the chairmen of committees constitute the bureau which assists the president in directing the conference. No definite rules regarding the presidency are recognized. Usually the chief delegate of the host or the initiating country is elected. If several countries sponsor a conference, the chief delegates of these countries may rotate the presidency (United Nations Conference on International Organization, 1945). The credentials of delegates are exchanged (at a small conference) or examined by a credentials committee which reports to the conference whether they have been found in "good and due form." Next, rules of procedure are drafted and adopted. They deal with such matters as secretariat, records, voting, publicity or secrecy of meetings, languages, order of speakers, resolutions and amendments, closure of debate, etc. In principle these

rules are adopted unanimously. The secretariat is usually headed by an experienced member of the host country's delegation who is elected secretary-general and who selects his staff from his own foreign office or from the participating delegations. The business of a large conference is transacted in plenary sessions and in committees, where most of the actual work is done, although it is subject to approval by the plenary sessions. The latter offer an opportunity for policy statements.

Each conference adopts its voting rules. The classic rule of international law requires a unanimous vote for all but procedural decisions. This principle was much criticized after 1907 on the ground that if any participating state can veto decisions, it endangers the conference as a method for the progressive development of international law and institutions. After World War I there was a trend toward majority voting; and it prevailed in organizations and conferences during and after World War II. This facilitates the adoption of treaties at conferences but does not ensure signature or ratification as there has been no departure from the principle that no state can be bound without its consent.

From the 17th century to World War I, French was the diplomatic language. Between 1919 and 1939 French and English predominated although German and Italian were also used. After World War II French, English, Spanish, Chinese and Russian were accepted as official languages at many conferences and in the United Nations; but the first two remained "working languages." This intrusion of linguistic nationalism into conference proceedings made them more protracted and more expensive. In multilingual meetings a system of simultaneous interpretation is used by means of telephone circuits running from the different interpreters to the delegates' seats.

Conference proceedings are recorded either in verbatim reports or in summaries. The former method is used for plenary sessions and the latter for committee debates. Verbatim and summary records are usually approved by the delegates before publication. Conference results are incorporated in treaties, conventions, declarations, recommendations or protocols. Sometimes a final act is adopted which summarizes the proceedings, lists the participating states and their representatives, as well as the treaties and other acts of the conference. Treaties and other acts imposing obligations are usually appended to the final act and are subject to separate signature and ratification. If the final act contains obligations it is also subject to ratification. In signing treaties an agreed order may be used, though often the *alternat* is adopted. According to this, each representative signs first the copy of the treaty intended for his state and other delegates sign in an agreed alphabetical order of their states. Sometimes the order of signature is determined by lot. When signing or ratifying a treaty governments may attach a reservation, that is, a formal statement to the effect that a particular provision shall not be binding on that state.

After the establishment of the League of Nations in 1920, many conferences were convened by it, by its successor the United Nations or by other international organizations. Such conferences were usually well prepared as the convening organization attends to all preliminary and "housekeeping" functions.

**CONFESSION.** Most religious groups within the Jewish-Christian tradition regard confession or the acknowledgment of sinfulness as a necessary condition for winning divine forgiveness. In the Old Testament the Lord said to Moses: "Say to the people of Israel, When a man or woman commits any of the sins that men commit by breaking faith with the Lord, and that person is guilty, he shall confess his sin which he has committed" (Num. v, 6). The mission of the prophets was to awaken in the people a sense of sinfulness and an acknowledgment of their guilt both personal and collective. The Psalter abounds with instances of such personal and corporate confession, and Ps. li is the classic expression of the sinner's realization that he must confess that he has sinned

before the Lord. This avowal of guilt, at times public, at times secret, appears to be the normal preparation for the expiation of sin and its atonement. Before the destruction of the Temple (A.D. 70) the sin offerings on the Day of Atonement (Yom Kippur) were prefaced by a collective expression of sinfulness (Lev. xvi, 21), and even after the destruction of the Temple, the Day of Atonement has continued as a day of prayer, fasting and confession.

In the New Testament the public ministry of Jesus is prepared by the baptism of John, a baptism unto repentance, accompanied by a public confession of sins (Matt. iii, 6) and the New Testament is brought to a close by the apostle John's assurance: "If we confess our sins, he is faithful and just, and will forgive our sins and cleanse us from all unrighteousness" (I John i, 9). There is no direct evidence in the New Testament that confession had to be specific or detailed or that the confession had to be made to a priest. The scriptural foundation for subsequent Christian practice and teaching is usually found in the authority given by Christ to the apostles to bind and to loose (Matt. xvi, 19; xviii, 18) and to forgive and to retain sins (John xx, 23). It is argued that the authority given is clearly discretionary and implies a knowledge of what to bind and what to loose, knowledge that ordinarily can be supplied only by the sinner's confession. In any event, a detailed confession of sins to the bishop or the priest-penitentiary appears quite early in the church's discipline of penance.

**Discipline of Penance.**—The word penance can refer to the sinner's repentance, to the works of satisfaction imposed by the confessor or freely undertaken by the penitent, or to the whole discipline of penance leading up to and including the sinner's reconciliation. In the early 3rd century this discipline was called *exomologesis* ("confession"). Thereafter, the discipline was known in the east and west as penance. The discipline for the first five centuries was not everywhere uniform, but it followed a general pattern that reflects the action of St. Paul in delivering a serious offender over to Satan "for the destruction of the flesh," and later in pardoning him or a similar offender lest he be "overwhelmed by excessive sorrow" (I Cor. v, 5; II Cor. ii, 7). Accordingly, there were two stages in the discipline of penance: excommunication, an exercise of the power of binding; and reconciliation, an exercise of the power of loosing. That this power affected the sinner's relations with God and not merely with the church is suggested by Christ's commission: "whatever you bind on earth shall be bound in heaven, and whatever you loose on earth shall be loosed in heaven" (Matt. xviii, 18).

Although Christ's commission to bind and to loose is given in the most general terms, there is early evidence that not all bishops were prepared to loose or to reconcile those guilty of apostasy, adultery and murder. When, however, this policy of harshness was interpreted by the Montanists and the Novatianists of the 3rd century as an implicit denial of the church's competence to forgive, the church intervened and at the first ecumenical Council of Nicaea (A.D. 325) condemned not only the practice but the teaching of these early extremists.

Except in the case of the recalcitrant sinner, excommunication was medicinal and normally led to pardon through the ministry of the bishop or, in emergency cases, through the ministry of a presbyter or simple priest. Even in the case of lesser sins, excommunication entailed separation from the Eucharist; in the case of more serious crimes, such as apostasy, adultery and murder, excommunication involved enrollment in the order of penitents, an order that corresponded to the grade of catechumen (*q.v.*) in the discipline leading up to baptism. In the graded discipline of the east a serious offender usually passed through four successive grades before being allowed to receive the Eucharist: (1) as a mourner the sinner prostrated himself in tears outside the doors of the church and sought the intercession of the clergy and people as they entered; (2) as a hearer, he was allowed to enter the church and to remain for the reading of the lessons and the bishop's homily; (3) as a kneeler or penitent in the strict sense of the term, he was the object of special prayers said over penitents while prostrate, after which he was dismissed from the assembly; (4) as a bystander, he was allowed to remain for the eucharistic liturgy but he was not privileged to make his offering or to receive Holy

**Communion.** In the west there seems to have been but one grade, that of kneeler or penitent.

Enrollment in the order of penitents followed upon confession to the bishop or, in the more populous churches, to the priest-penitentiary, whose office it was to assign the period of penance and to oversee its fulfillment. Whether the penitent was obliged to manifest publicly the sin or sins for which he was doing penance is not certain. Tertullian (c. A.D. 200) seems to have public confession in mind when he rebukes those who put off confession, "more mindful of their embarrassment than of their salvation. . . . As if by withdrawing anything from the knowledge of men we shall conceal it from God as well" (*De Paenitentia*, x). However, the 5th-century Greek historian Socrates informs us that the priest-penitentiary was appointed from the earliest times because bishops decided that "it was too much of a burden to announce one's sins as in a theatre with the congregation of the Church as witness" (*Ecclesiastical History*, vii, 16). Again, the local Italian practice of reading from a chart the sins of the penitent is regarded by Leo I the Great (c. A.D. 450) as a "defiance of apostolic rule" (*Epistles*, clxviii).

In the 5th-century discipline of the Roman Church, the practice was to hear confessions in the beginning of Lent and, unless sickness or some other emergency arose, to reconcile the penitents on Holy Thursday. After confession, the sinner was clothed in goats' hair, sprinkled with ashes and received into the order of penitents by an imposition of hands. Although the evidence is not conclusive, it would appear that the penitent was excluded from the eucharistic liturgy along with the catechumens until Holy Thursday, when he was once more privileged to make his offering and to receive the Eucharist. During the period of penance, which appears to have been considerably shorter in the Western Church than in the Eastern Church, the penitent was obliged to fast and to multiply his prayers. To compensate, perhaps, for the abbreviated period of penance in the west, disabilities were introduced that affected the penitent for life. Thus, the reconciled penitent was not ordinarily permitted to marry, or, if married, to resume marital relations; he was forbidden to engage in public trade and to undertake military service. Failure to observe these penalties reduced the penitent to the status of the bystander in the graded discipline of the east.

In the east, public penance did not long survive the action of Nectarius, patriarch of Constantinople, in abolishing the office of priest-penitentiary (A.D. 391). Serious sinners were no longer enrolled in the order of penitents nor were they excluded from the eucharistic liturgy. They were forbidden, however, to receive the Eucharist until their penance was fulfilled, a status that reflects the grade of bystander in the earlier discipline.

In the east and the west, public penance, modeled as it was on the discipline of the catechumenate, could be undergone but once. Whether or not there was a private penance for those guilty of sins that were secret or that fell short of the canonical triad (apostasy, gross impurity and murder) is still debated. Most historians are of the opinion that private and repeated penance was introduced first in the churches of the Celtic lands, and that it was through the influence of Irish monks and English missionary scholars that private penance won acceptance on the continent. In any event, by the year 850 and as a result of the Carolingian reform, the principle of "public penance for public crimes, private penance for secret sins" became the established rule. Gradually, too, was introduced the practice of reconciling or absolving sinners immediately after confession and before the fulfillment of penance, so that by the close of the 11th century only public or notorious sinners were reconciled in the solemn penance of Holy Thursday.

Although the discipline of penance was regarded in the early church as a second and more laborious baptism, those guilty of serious sins usually put off penance until death approached. To correct this abuse, the fourth Lateran council (A.D. 1215) established the following rule: "Let everyone of the faithful of either sex, after having reached the age of discretion, faithfully confess in secret to his own priest all his sins, at least once a year. . . ."

**Modern Teaching and Practice.**—The Roman Catholic Church teaches that penance is a sacrament, instituted by Christ,

in which an integral confession of all serious sins committed after baptism is necessary by divine precept. Although venial sins need not be confessed to the priest, confessions of devotion are encouraged and are widely practised. The doctrinal position of the Eastern Orthodox Churches on the sacramentality and necessity of confession to a priest agrees with that of the Church of Rome.

Among Lutherans private confession and absolution survived the Reformation for a time. The Augsburg Confession of 1530 not only listed penance along with baptism and the Lord's Supper as sacraments of the New Law but asserted that "it is not customary to offer the Lord's body to those who have not first been examined and absolved." Luther himself was anxious that private confession be retained, and in his Short Catechism he drew up for the use of "simple folk" a method of examining their consciences and of confessing such sins "as we know and feel guilty of in our hearts." The instruction is followed by a rubric for the confessor, who is to use the then current formula: "I forgive thee thy sins in the name of the Father, the Son and the Holy Ghost. Amen. Go in peace." Calvin too recognized the value of private confession and absolution for those troubled in conscience, but he denied that such confession was sacramental or that it was necessary for the forgiveness of sins. Although there is a small but growing movement among German Lutherans and French Calvinists to restore the practice of private confession, most Protestants regard the general confession and absolution of the communion service as a sufficient preparation for the Lord's Supper.

The Church of England resisted to some extent the attempts of the Nonconformists to have all reference to private confession and absolution removed from the prayer book. Thus, in the Order for the Visitation of the Sick, the sick person "shall be moved to make a special confession of his sins, if he feels his conscience troubled with any weighty matter." The same directive is found in the Book of Common Prayer as used in the Protestant Episcopal Church in the United States. The Oxford movement in the 19th century fostered a revival of private confession even in times of health, a practice that has received some acceptance among Anglo-Catholics. However, many Anglicans and Episcopalians look with disfavour upon "romanizing" tendencies within their churches and favour the general confession and absolution of the communion service.

Confession of a generic nature plays an important role in most fundamentalist and Pentecostal churches, and the 1920s witnessed the rise of a new religious group, the Buchmanites, among whom a public and detailed confession of sins is regarded as the first step toward a sincere conversion (see MORAL RE-ARMAMENT). Nor has the strictly therapeutic value of confession been overlooked by the psychiatrist, whose demands upon the sincerity and frankness of his patient are no less exacting than those made of the penitent in the early church. (See also ABSOLUTION.)

The term confession is used also to designate the tomb of a martyr and the building erected over the tomb (see CRYPT).

(P. F. P.)

**CONFESSION**, in the criminal law, is an extrajudicial statement acknowledging guilt of an offense. Both the common law and U.S. constitutional law require that coerced or involuntary confessions be excluded from the evidence admitted in a criminal trial (see THIRD DEGREE). While a voluntary confession is competent evidence of guilt, it is not ordinarily regarded as sufficient evidence of guilt. Thus, in most jurisdictions the confession must be corroborated by other evidence before a defendant may be convicted. Ordinarily the corroborating evidence must relate to the corpus delicti; that is, it must establish that a crime was committed by someone. See CRIMINAL LAW; EVIDENCE. (F. A. A.)

**CONFESSIONAL**, in Roman Catholic churches, is a box, cabinet or stall in which the priest sits to hear the confessions of penitents. The confessional is usually a wooden structure, with a compartment (entered through a door or curtain) in which the priest sits, and on one or both sides another compartment or compartments for penitents; this is separated from the priest's compartment by a partition, with a latticed opening for the penitent to speak through, and contains a step on which he kneels. By this arrangement the priest is hidden; the penitent may or may not be visible to others. Confessionals usually form part of the architectural scheme of the church, but sometimes they are movable pieces of furniture.

In its present form the confessional dates no farther back than the 16th century. Previous to that time, the priest normally administered the sacrament in its private form while seated on a chair in some part of church; the penitent stood or sat beside him, and knelt for the absolution. Since the prevailing rite of absolution demanded that the priest lay his hand on the penitent's head, there could be no separating wall or curtain. From the 11th century, the chair was placed "in front of the altar," probably within the chancel. St. Charles Borromeo in 1565 ordered that a metal grill separate priest from penitent in his archdiocese of Milan. This practice spread rapidly, and, after adoption into the Roman Ritual under Pope Paul V in 1614, soon became universal. Thus the essentially public nature of the sacrament was safeguarded, and a reasonable privacy assured. In baroque churches the confessional often developed into a highly ornate structure.

According to modern canon law, women's confessions may be heard only in a confessional in church; men may go to confession outside church, but when confession is heard in church, the confessional should be used.

In Eastern Orthodox churches the confessional is unknown, but it is becoming customary in some of the churches of oriental rite united to Rome. With the revival of auricular confession in some Anglican and Lutheran churches, a confessional chair, with or without separating grill, is finding gradual acceptance.

Golzio, "Confessionale," in *Enciclopedia Cattolica*, vol. iv (1950); E. Jombart, "Confessional," in *Dictionnaire de droit canonique*, vol. iv (1949). (G. L. D.)

**CONFESSIONS OF FAITH, PROTESTANT.** The medieval Christian church did not attempt an official codification of its doctrine. The creeds inherited from antiquity (Nicene Creed) or formulated in the early middle ages (Apostles' Creed, Athanasian Creed) were used in liturgical worship to confess the Christian faith (*see* CREED). Certain doctrinal points were defined by councils as a result of doctrinal controversies. A decree on the seven sacraments issued by the Council of Ferrara-Florence in 1439 was a statement concerning one important part of the doctrinal system. But there was still no codification of doctrine. Nor did the heretical movements in the middle ages produce comprehensive declarations of faith.

The Reformation in the 16th century led to the formulation of declarations aiming at a definition of all the main points of the doctrinal system. Most of these documents were compiled with the purpose of expressing the Church's doctrine; a few of them originally served other purposes (*e.g.*, Luther's catechisms) but were soon given the rank of doctrinal standards.

The first confessional documents of the Reformation were the drafts preceding the Augsburg Confession of 1530. This example set by the Lutherans was followed by the other Reformation

churches, and it was even followed by the Council of Trent (1546-63), whose decrees and canons, together with the *Profectio ad Tridentina* of 1564, were a codification of Roman Catholic doctrinal tenets.

#### Motives Underlying Protestant Declarations of Faith

A variety of motives underlay the elaboration of Protestant confessions of faith in the Reformation era as well as in post-Reformation times. Their obvious purpose is to give expression to convictions held by groups claiming to be the legitimate Christian Church. "We believe" are the opening words of most of the articles of the French Huguenot confession of 1559. "We believe, confess and teach" is a wording which constantly recurs in the Lutheran Formula of Concord. Such declarations frequently contain arguments in support of the tenets confessed. Accordingly they serve also an apologetic purpose when they intend to prove the orthodoxy of the doctrines professed by Protestant churches.

This motive is particularly conspicuous in the Augsburg Confession, which refers to the creeds and repeatedly quotes the Fathers of the early church besides recurring to arguments from Scripture. It is said expressly that the Lutheran teaching does not differ from the Scriptures or from the Catholic Church "or from the Roman Church, as it is known from the (ancient) authors." The whole controversy with the contemporary Roman Church is here reduced to a dissension over "certain abuses." The sequel to this document, the Apology for the Augsburg Confession, contains an elaborate theological motivation of the tenets held by Lutherans. The Formula of Concord is a large book containing theological reasoning. Whereas the Lutheran documents, in spite of their emphasis on the Scriptures as their sole authority, argue from the early Fathers as well as from Scripture, the corresponding Reformed confessions argue from Scripture alone.

The purpose of some documents from the 16th century was to create unity between various Protestant parties. The Marburg Articles of 1529 were an attempt to unite Luther and Zwingli. The Wittenberg Concord of 1536 aimed at the formulation of a eucharistic doctrine acceptable to Lutherans and the Swiss Reformers alike. The purpose of the Ten Articles compiled at the order of Henry VIII of England was to facilitate his approach to the Lutheran princes in Germany. When such attempts had proved abortive and the schism between the Protestant churches was an irreparable fact, confessional documents of a similar type were occasioned by internal dissensions in the separate churches. The Formula of Concord was a successful attempt to restore unity within the Lutheran Church after three decades of internal struggle over doctrinal questions. The Canons of Dort served a similar purpose in the Dutch Reformed Church. Documents of the last type aim expressly at establishing a norm for the teaching of the church. The same use, however, had been made of the older confessional documents from an early date. The Wittenberg Concord required of a doctor of theology included from 1533 onward acquaintance to the doctrines of the Augsburg Confession, and so did also the ordination vow in Saxony from 1535.

The titles given to the various Protestant confessions reflect this variety of motives: "confession" (*e.g.*, the Augsburg Confession, the French *Confession de Foi*, *Confessio Belgica*, the Scottish Confession of Faith, the Westminster Confession), "articles" (*e.g.*, Marburg Articles, Schwabach Articles, the various versions of articles of religion in England), "declaration" (*e.g.*, the Savoy Declaration), "consensus" (*e.g.*, *Consensus Tigurinus*), "concord" (*e.g.*, Wittenberg Concord, the Formula of Concord, the Book of Concord). A few of them bear the name of "catechism," first introduced as a book title by Luther and adopted by Calvin (*e.g.*, *Catéchisme de l'église de Genève*) and his followers (*e.g.*, Heidelberg Catechism, the two Westminster catechisms) and even by the Roman Catholic Church (*e.g.*, *Catechismus Romanus*, 1566). Before Luther, "catechism" meant oral catechetical instruction. In the Lutheran Church there was a tendency to attribute to the confessional writings (*Bekennnisschriften*) of the 16th century an authority similar to that possessed by the creeds, and accordingly to call them "symbols" of the church, a name which in earlier times had been reserved for the creeds. It even became customary to

BAROQUE CONFESSIONAL OF THE CHURCH OF S. BERNARDO, PIEDMONT, ITALY; 1692

speak of these lengthy theological treatises as the "symbolical books" of the Lutheran Church.

**Lutheran Churches.**—The *Augsburg Confession* (*Confessio Augustana*).—This declaration, signed by the Lutheran princes and independent cities in Germany, was presented to the emperor Charles V on June 25, 1530, during the diet of Augsburg. As the emperor needed the support of the Lutheran territories in his war against the Turks, he had decided to overcome the religious schism in Germany through peaceful deliberations. He now wanted to hear both parties. Before the diet the Lutheran elector of Saxony had asked his theologians to prepare a memorandum on the changes introduced in his church, known as the Torgau Articles. In Augsburg, however, the Lutherans were confronted with an accusation of heresy from the Roman Catholic side which compelled them to rewrite and expand their short apology. As Luther was an outlawed person who could not make his appearance at Augsburg, this task fell to Philipp Melancthon. Melancthon included matter from the Marburg Articles of 1529 and from the Schwabach Articles, drawn up in 1529 as a basis for a defense union of the Evangelical princes. But to a large extent he had to formulate independently. The draft was sent to Luther and received his full approval.

The Augsburg Confession is extant in a German and a Latin version, both handed over to the emperor. The two original manuscripts are lost. Six printed editions of the German and one of the Latin text appeared while the diet was in session. As these were inaccurate, an official *editio princeps* was published by the author himself in 1531. The confession bears the stamp of Melancthon's moderation and caution and reveals the threatening situation in which it was compiled. The emphasis is laid on the catholicity and orthodoxy of the Lutheran interpretation of Christianity, especially in the first 21 articles dealing with doctrine. The central ideas of the Lutheran Reformation, however, have received a classic formulation: the doctrine of salvation by faith alone, its relation to good works, the doctrine of the church and the sacraments, the new evaluation of matrimony and of secular society and its laws. In the second part, comprising seven articles on abuses which had been abolished, certain customs and doctrines of Roman Catholicism are criticized in strong terms.

No recognition of the Lutherans by the emperor was attained at Augsburg. The Evangelicals left the diet and had to prepare themselves for the civil war which seemed to be inevitable. In this situation, the Augsburg Confession became the rallying banner of the Lutheran princes and the norm for doctrine in their churches. Melancthon, however, introduced minor alterations in the new editions of the confession which appeared after 1531, treating the book as his private work. In the edition of 1540 he went so far as to redraft article 10 in order to approximate to Calvin's doctrine of the Eucharist. When the south Germans who had Calvinistic leanings began to quote this edition as authoritative, it was stigmatized in Lutheran circles as the *Augustana variata*, and the use of the "unaltered Augsburg Confession," *Augustana invariata*, was enjoined.

The Lutheran Reformation was at last recognized by the German *Reich* in the Peace of Augsburg in 1555, which acknowledged the coexistence of "the religion of the Augsburg Confession" and "the old religion." Protestant movements which did not conform to this confession were not allowed, but as the peace treaty did not expressly mention the "unaltered" confession there was room for the Calvinizing party, which could make claims to legitimacy by invoking the authority of the *variata*.

Thus historical events gave a unique importance to the Augsburg Confession. It was recognized also in the Lutheran churches outside Germany as an authoritative standard of doctrine (Denmark and Norway, 1574; Sweden and Finland, 1593) and in the 20th century is the doctrinal standard of all Lutheran churches and the unifying bond of Lutheranism. (See also AUGSBURG CONFESSION.)

*Luther's Shorter and Longer Catechisms* (1529).—Both these catechisms, written in the spring of 1529, were produced in order to teach children and adults the elements of Christian faith. For more than two centuries the Shorter Catechism was used as the

chief reader in primary schools and even frequently formed the basis for sermons. In the Formula of Concord the two catechisms are called "the layman's Bible" and in the Book of Concord they are given the status of confessional standards.

*Schmalkaldic Articles* (1537).—These derive their name from the defensive league formed by the Lutheran princes at Schmalkalden in 1531. They were written by Luther for presentation to a projected council Pope Paul III had summoned to Mantua in 1537. The elector of Saxony did not approve the idea of the Evangelicals' appearing at the council, and to clarify their position he commissioned Luther to compile the articles of faith from which he would in no circumstances depart. The tone of the document therefore became particularly anti-Roman. It was subscribed by the Wittenberg theologians. Melancthon, however, accompanied his signature with a reservation, and he also prevented the document from being signed by the princes as their official declaration. The more militant Lutherans valued the Articles highly and they were included in the Book of Concord.

*Formula of Concord* (1577).—The Formula was the result of protracted theological discussion arising out of the controversies which rent the Lutheran Church after Luther's death in 1546. The chief authors were Jacob Andreae and Martin Chemnitz, who combined a central position in the internal controversies with a marked hostility toward Calvinism and Roman Catholicism. The Formula is an extensive book which inaugurates the era of Lutheran orthodoxy.

*Book of Concord* (1580).—In the years of struggle over doctrinal issues the idea of a codification of the authoritative confessions gained support from the Lutheran theologians and princes. The most extensive of these collections was the Book of Concord, published in 1580 and adopted by 51 princes and 35 cities in central and south Germany as the norm for teaching in their churches. The book contains the three creeds (the Apostles', the Nicene and the Athanasian) together with the documents listed above and Melancthon's Apology for the Augsburg Confession, written during the diet of 1530 and published in 1531.

The Book of Concord was never recognized in Denmark and Norway. When the legislation of these countries was codified in the late 17th century under Christian V only the three creeds, the Augsburg Confession and the Shorter Catechism were declared to be the standards of doctrine. In Sweden, the Synod of Uppsala in 1593 proclaimed the Augsburg Confession to be authoritative, whereas the whole Book of Concord was enjoined by the church law of 1686. (See also CONCORD, BOOK OF.)

**Reformed Churches.**—Within the churches that have received their stamp from Calvin's Reformation a large number of confessions have been promulgated. In these churches, however, confessional documents have not played the same part as the "symbolical books" of Lutheranism. This is partly due to their view of the authority of Scripture, which relegates articles of faith to the position of "subordinate standards," and partly to the historical fact that the Reformed churches have never been united in accepting a common confessional document.

The First Helvetic Confession of 1536, approved by all Evangelical cantons in Switzerland, bears the stamp of a moderate Zwinglianism.

Calvin's Geneva Catechism of 1542 is a short summary of his teaching in questions and answers (see CATECHISM: Reformed).

The most important Swiss confessions are the *Consensus Tigurinus* of 1549, whereby Calvin and the followers of Zwingli entered on a union, and the Second Helvetic Confession, compiled by Heinrich Bullinger as a private work, but recognized in 1566 by all the Reformed cantons as well as by the elector Frederick of the Palatinate. This confession was for some time regarded as authoritative also in France, Scotland and Poland. Here the Zwinglian doctrine of the Eucharist has been superseded by Calvin's teaching. (See also HELVETIC CONFESSIONS.)

In France the Reformed Church formulated its confession of faith at a general synod held at St. Germain in 1559. The draft of this *Confessio Gallicana* came from Calvin's hand. It is distinguished for its elegance and clarity. The doctrine of predestination is lucidly expounded.

The *Confessio Scoticana* of 1560 was compiled in English in four days with John Knox as its principal author. The document was approved by the Scottish parliament. A special feature is the emphasis on church discipline and on the theocratic ideal.

The Heidelberg Catechism of 1563 was due to the initiative of the elector Frederick III of the Palatinate. He had become convinced that the Lutheran eucharistic doctrine was "papist," went over to the Reformed standpoint and transferred the ecclesiastical allegiance of his territory, in accordance with the generally acknowledged principle of his time that the subjects should follow their prince in religious matters (*cuius regio, eius religio*). He commissioned Zacharias Ursinus, a Melancthonian, Caspar Olevianus, a moderate Calvinist, and others to compile a confession which received the form of a catechism. The tone is conciliatory toward Lutheranism but polemical toward Roman Catholicism. No express mention is made of predestination. The Heidelberg Catechism was accepted in Switzerland, Hungary and Scotland and is one of the very few Reformed confessions to which reference is made today. (See also HEIDELBERG CATECHISM.)

In the Netherlands, a Reformed confession of faith was adopted by a synod held at Antwerp in 1566. The *Confessio Belgica* is the last continental confession of this type.

In the 17th century it fell to the Dutch Reformed Church to formulate the doctrine of Calvinist orthodoxy in the Canons of Dort (Dordrecht). This document was occasioned by a doctrinal controversy over predestination. A liberal minority, named Arminians after their leader Jacobus Arminius, rejected the doctrine of absolute predestination and taught that Christ had died for the whole human race, that the possibility of salvation was offered to all men, that man was in need of God's regenerative grace, but could resist the grace of God, and that he could fall from grace. The majority of theologians and pastors in the Netherlands kept to the strict doctrine of predestination, which declared God's grace to be irresistible and left no room for human liberty in the process of salvation. In 1618 the state authorities summoned a national synod to Dordrecht. It was attended also by theologians from Switzerland and Germany and even by five official representatives from the Anglican Church, at that period reckoned among the Reformed churches. The synod declared the Arminians to be heretics, and in 1619 it formulated the strict doctrine of predestination in 93 canons. The primary religious concern of the Canons of Dort was to proclaim the majesty of God and to safeguard the assurance of salvation. Outside Holland, the canons were formally adopted by the French Reformed Church and received for information only by the other Reformed churches. (See also DORT, SYNOD OF.)

The Westminster Confession (q.v.) was compiled during the English Civil War. In 1643 parliament appointed a commission of 121 divines and 30 members of parliament, with the purpose of giving a Presbyterian constitution to the Church of England and of introducing uniformity in doctrine, worship and order throughout the British Isles. The commission held its meetings in Westminster abbey and was therefore known as the Westminster Assembly. The large majority of its members were Presbyterians, Calvinist in doctrinal matters. In 1646 a draft version of a confession of faith was completed and printed privately. It was studied by parliament in detail and published under the title of *Articles of Christian Religion approved and passed by both Houses of Parliament after advice had with the Assembly of Divines by authority of Parliament sitting at Westminster*. In Scotland the Westminster Confession was readily approved by the general assembly in 1647 and by the Scottish parliament in 1649. In England events followed another course. After the ecclesiastical chaos under the Commonwealth, Anglicanism was reinstated in 1660. The Westminster Confession did not become a doctrinal standard in the Church of England.

In addition to the confession, the Westminster Assembly issued two catechisms, the Shorter and the Longer, which are assigned the same degree of authority as the Westminster Confession in the Reformed Churches of Scotland and America. All three documents are remarkable theological works, lucid, precise and dignified in tone.

**Other Protestant Bodies.**—Congregationalism, according to its fundamental principles, is averse to the idea of establishing a doctrinal norm or of binding consciences to a confession. Such use of confessions "causeth them to degenerate from the nature and nature of confessions, and turneth them into Exactions and Impositions of Faith," it was expressly stated when a "meeting of Elders and Messengers," held in 1658 at the Savoy, London, produced their classical *Declaration of the Faith and Order owned and practised in the Congregational Churches in England*. In doctrinal matters, the Savoy Declaration differs only slightly from the Westminster Confession. When the British Congregationalists formed the Congregational union, a new declaration was issued (1833). For the first time it is stated in a document of this official character that the Scriptures "consulted with the aid of sound criticism" should be the final court of appeal in doctrinal questions. On the rare occasions when Congregationalists have published statements on their tenets, they have pointed out that such statements are only a presentation of what is commonly believed in their churches, not a doctrinal law.

The Baptist churches share this attitude to human standards of doctrine. Attacked by their adversaries, however, they felt compelled to produce official statements on doctrine. In 1644 these English Baptists who adhered to the Calvinist doctrine of predestination issued a confession of faith, followed by a similar document in 1677, which was approved by the Federation of American Baptists at Philadelphia in 1742. In 1660 the Arminian wing of the English Baptists produced their own declaration of faith.

The unwillingness to invest such declarations with the authority of articles of faith has always been alive in Baptist circles. In the controversy over liberal theology which broke out among British Baptists in 1887, their great preacher, C. H. Spurgeon, urged the Baptist union to adopt a declaration of faith in the basic truths of evangelical Christianity. His proposal was rejected as being incompatible with the Baptist attitude toward binding articles of faith.

The Methodist churches do not display the same aversion to credal statements. In addition to the Scriptures, they acknowledge the creeds and certain other "standards of doctrine" which are regarded as containing the doctrine of the church. These documents are not, however, articles of faith in the juridical sense. In the detailed legislation of the Methodist Church in America the confessional standards are never defined. The questions put to the candidates for the ministry at their ordination only refer to "the doctrines of the Methodist Church" without further specification. The documents considered as normative are: John Wesley's *Notes on the New Testament* (1755); a collection of 44 of his sermons, called the *Standard Sermons*; and (in American Methodism) Wesley's 25 articles of 1784, an abridgement of the Anglican 39 Articles, which through omissions and the rephrasing of certain expressions have been made more Protestant and at the same time less Calvinist (admitting of Arminianism) and purged from references to general councils or to the establishment. The first two of the above documents differ in literary form and in preciseness from what are traditionally called confessions of faith.

The Quakers refuse to subscribe to articles of faith. When the Society of Friends in England published a statement on their beliefs in 1920, occasioned by the necessity of defining their attitude to the ecumenical movement, it was meant only to be a description of views commonly held by Quakers, not a norm for doctrine. The same character attaches to the three small volumes of representative pronouncements of leading Quakers covering the whole period of their history, which were published by the English Society of Friends (*Christian Life, Faith and Thought in the Society of Friends*, 1921-31).

**Attitude of Protestant Churches Toward Their Confessions.**—Even in churches which in principle are opposed to confessional obligation the necessity of formulating doctrinal statements has been felt on certain occasions; the attempt has been made, however, to formulate guiding principles without making such statements a binding law. In the churches which consider their confessions as doctrinal standards the confessions have caused some difficulties in modern times.

The juxtaposition of Holy Scripture and confessional documents implies a theological problem which was discussed in the 17th century but could not become acute so long as the two authorities were felt to be concordant. Orthodox Lutheran theology maintained that Holy Scripture was the supreme authority (*norma normans*), while the confessions derived their authority from their concordance with Scripture and were a secondary norm (*norma normata*). This doctrine could not create difficulties to churchmen who were convinced that their own church possessed the only right understanding of the Bible.

In the 18th century, pietism and the enlightenment were both averse to a confessionalism requiring the acceptance of every article of the confessional standards. It became customary to distinguish between fundamental and nonfundamental doctrines and to practise a large amount of individual liberty with regard to confessional documents. Critical exegesis, acquaintance with other Christian traditions and studies in the history of dogma created a spirit of confessional relativism. Toward 1800 there was a considerable liberty of interpretation without formal abolition of confessional obligation for pastors and teachers.

After 1800, and especially after 1830, a wave of confessionalism in the Lutheran and Reformed churches re-established the ideal of loyalty to the church's confession. Representatives of this school tried to check rationalism and liberalism by requiring submission to the confessional standards. On the other hand, biblical scholarship and historical studies revealed the differences between biblical theology and the doctrines of the confessional documents. Theology became to a large extent permeated by a nondenominational spirit, and many churchmen felt difficulties in subscribing to creeds and confessional documents. In the Swiss Reformed churches the problem received a radical solution between 1870 and 1880 when a new ordination vow was introduced, without any reference to the creeds or to the confessional documents. In other churches it was generally accepted that confessional loyalty means loyalty to "the idea and spirit" of the doctrinal standards. In many Lutheran churches the ordination vow was rephrased to the effect that the ordination candidates should promise to teach the Word of God "as it is revealed in Holy Scripture, and as it is witnessed to by our Church in its Confession." In all Lutheran and Reformed churches, there was also a party which required an unconditional acceptance of the doctrines contained in the confessions.

After World War I a renaissance of confessionalism could be observed in both Lutheran and Reformed churches, and accordingly a new interest in the classical confessions. The fight of these churches against Nazi dictatorship in Germany strengthened this confessionalism. Loyalty to the church's confession became a catchword and a rallying banner. The fight also occasioned new declarations of a type similar to those of the Reformation era. The German Confessional Church (*Bekennende Kirche*) issued a statement known as the Barmen Declaration of 1934, containing theses on the message of the Church (see BARMEN, SYNOD OF). In Norway, a document entitled *Kirkens grunn* ("The Church's Foundation") was read from the pulpits in 1942 and was signed by all pastors who were on the church's side in its conflict with the Nazi regime. Such documents were considered as having the authority of confessional standards. But when normal conditions were re-introduced after the end of World War II, subscription to these documents was no longer required. No expansion of the traditional collections of confessional standards took place. See also CATECHISM.

**CONFESSOR**, (1) a title of honour given to certain Christian saints; and (2) a member of the Christian clergy who receives the confession of a penitent's sins and imparts absolution.

During the persecutions of the 2nd century the title of confessor was given to those Christians who had declared their faith before the Roman tribunals but had not suffered martyrdom. When the persecutions ceased in the 4th century the title and veneration given to confessors were extended first to bishops who had defended the faith of the church against heresy and then to Christians who were judged to have given extraordinary evidence of Christian virtue and thus to have "confessed Christ." Since the middle ages "confessor" has been used in this last sense to designate any canonized male saint who is not a martyr (see also SAINT).

For confessor in the second sense, see CONFESION.

(J. W. HE.)

**CONFIDENCE GAME**, the term popularly applied to any elaborate swindle, particularly one that exploits the cupidity of the victim. Some U.S. jurisdictions have created a statutory offense of this name. Although the elements of the offense are not clearly defined by this legislation, the offense may be regarded as an aggravated form of the misdemeanor known as false pretenses. The essential element of the crime of confidence game is the betrayal of the trust and confidence deliberately induced in the victim by the offender with fraudulent purpose. See FRAUD.

(F. A. A.)

**CONFIRMATION**, a Christian rite by which the relation between man and God established in baptism (*q.v.*) is said to be confirmed. During the first several centuries of Christian history, when most of the accessions to the church were adult converts from paganism, the baptism of these adults and the ceremony admitting them to the full rights of membership (equivalent to, but not yet called, confirmation) probably coincided. Early Christian theologians, therefore, do not accord much special treatment to the rite of confirmation, but closely connect its meaning and effects with those of baptism. But as the baptism of infants rather than of adults came to be customary, a sharper distinction between baptism and confirmation became necessary; and in all those Christian denominations where some sort of confirmation is still observed, its connection with baptism and its distinction from baptism shape both the practice of the rite and the theological interpretation placed upon it.

In the Roman Catholic Church confirmation must be at the hands of a bishop, except in certain exceptional cases where a priest is granted permission to perform the rite. A baptized person who has come to the age of reason (at least 7, though in practice not until age 11 or 12) receives the laying on of hands from the bishop and is anointed with the sacred chrism on his forehead. The bishop pronounces the formula: "I sign you with the sign of the cross and confirm you with the chrism of salvation, in the name of the Father and of the Son and of the Holy Spirit," and he gently strikes the cheek of the candidate as a sign of the spiritual warfare in which he is now to engage as a knight of Christ. According to Roman Catholic doctrine, confirmation is a sacrament instituted by Jesus Christ, and it confers the gifts of the Holy Spirit, grace, strength and courage upon the recipient.

The Eastern Orthodox churches, as well as some of those eastern churches in communion with Rome, permit an ordinary priest to administer confirmation, but with a chrism consecrated by a patriarch or bishop. As a rule, confirmation in Eastern Orthodoxy follows immediately upon baptism, as part of the same service, and is followed in turn by the first communion of the child, who thus receives all three sacraments together.

Controversy between east and west over confirmation dealt principally with the question of who may ordinarily administer the sacrament. The paucity of references to confirmation in the early Christian tradition has aroused controversies also among Roman Catholic theologians as to whether Christ determined in detail the "matter" of confirmation (see SACRAMENT), or whether

the apostles or the church added the rite of anointing to the laying on of hands.

Of the communions to emerge from the Reformation, Anglicanism and Lutheranism retained a form of confirmation, but with notable divergences from the early and Roman Catholic rite. The Anglican practice is to restrict the right of administering confirmation to the bishop, who lays hands upon the candidate and says: "Defend, O Lord, this thy child with thy heavenly grace, that he may continue thine forever; and daily increase in thy Holy Spirit more and more, until he come unto thy everlasting kingdom." The problem of the connection between baptism and confirmation and the inconclusive evidence about the early Christian practice of confirmation have been the occasion for theological controversy within Anglicanism over the independent sacramental status of confirmation as "the seal of the Spirit."

Lutheranism, in general, restricts the term "sacrament" to baptism and the Eucharist, and therefore rejects the sacramental definition of confirmation, making of it instead the public profession by the candidate of the faith into which he was baptized as an infant. Confirmation in Lutheran usage, as in Anglican usage, is therefore preceded by instruction in the catechism (*q.v.*).

Other Protestant bodies sometimes use the term "confirmation" for their acceptance of baptized members into the duties and privileges of full membership, including the right to receive the Eucharist.

Hesburgh, *The Relation of the Sacramental Characters of Baptism and Confirmation to the Lay Apostolate* (1946); Lionel S. Thornton, *Confirmation: Its Place in the Baptismal Mystery* (1954); Geoffrey W. Lampe, *The Seal of the Spirit* (1951); Lukas Vischer, *Die Geschichte der Konfirmation* (1958). (J. J. PR.)

**CONFISCATION AND EXPROPRIATION**, in law, are terms applied to the compulsory transfer of private property to public ownership. Broadly speaking, the distinction between them consists in whether or not compensation is paid to the private owner. Confiscation involves taking without the payment of compensation; expropriation, on the other hand, normally implies such payment.

**Confiscation.**—The word confiscation derives from the Latin *fiscus* and means literally the adding of private property to the public treasury. The term originated in Roman law; and the practice gained in use as central political organizations acquired strength. The common-law concept of confiscation included three aspects: as a punishment for great crimes, as an act of the sovereign, and as a belligerent right against the property of enemies in war.

In the middle ages, confiscation developed into an important tool in the enforcement of the criminal law; since the criminal was seen as an enemy of society, his goods could rightly be appropriated to the common store. Forfeiture to the crown of the lands of persons attainted (*i.e.*, convicted and sentenced to death) of high treason thus gave rise to this form of confiscation (*see* **ATTAINDER**). Another example of confiscation in the medieval period was escheat (*q.v.*). Whenever a tenant of land was attainted of felony, his land was said to "escheat" (*i.e.*, fall back) to the feudal lord from whom he held. The doctrine of escheat was founded on the general principle of the feudal system that land should always be in the possession of someone; and an escheat occurred whenever a tenancy came to an end for whatever reason; *e.g.*, on the death of the tenant without heirs. There was a presumption that in the absence of proof to the contrary, the crown was the feudal lord and thus entitled to any land which escheated. With the decay of the feudal system and the disappearance of feudal lordships, this presumption operated more and more frequently, so that the crown became the chief recipient of escheated land. Escheat for felony, together with forfeiture to the crown, was finally abolished in England in 1870. However, although escheat for failure of heirs was also abolished in 1925, an escheat is still possible in certain circumstances.

In the early middle ages, property of subjects of an enemy nation was freely confiscated at the inception of warfare, but this practice declined with the rise of trade and commerce. *Magna Carta*

provided for immunity of property of merchants of enemy nations for a certain period following the beginning of the war, a practice which increased in scope. This concept has since widened to include almost all of society, and international law recognizes extensive restrictions upon confiscation by belligerents. Confiscation is deemed permissible only in the case of goods especially of use for war materials or subsidiary activities. While this standard is seldom met in full, the trend in this direction is evident in the modern practice of seizing private enemy holdings only for the duration of the hostilities. (*See* **LAW OF WAR**.)

The use of confiscation as an instrument of government power reached its zenith in the 16th and 17th centuries and has since declined. Its present use is ordinarily limited to the lawful use of the police power. An example is the seizure from private citizens of objects deemed obnoxious to public safety or unable to be put to a lawful use, such as gaming tables, fishing nets being illegally used, etc.

**Expropriation.**—Expropriation, unlike confiscation, is a flourishing and indeed expanding tool of modern government. The origin of the word expropriation is in the Spanish *expropiación*, which originally constituted the taking of private land for public use in any fashion. While the term is sometimes applied to the transfer of property from one private individual to another, expropriation is properly only the transfer from private to public hands and, under later usage, is specifically the acquisition of private property under the right of eminent domain (*q.v.*). As such, expropriation implies legal process and just compensation for goods or property taken for public use, with judicial redress as a remedy for inadequate compensation. Expropriation is not ordinarily a method of supplying the common needs of the government, but is directed toward the satisfaction of specific government objectives.

The right of the property owner to be adequately compensated for losses incurred by expropriation is recognized in international law and finds constitutional protection in many western nations. In the United States, the 5th amendment to the constitution provides that "no person shall be . . . deprived of life, liberty or property without due process of law; nor shall private property be taken for public use without just compensation." While this only limits the power of the federal government (*Barron v. Baltimore*, 7 Pet. 243), the U.S. supreme court has held that the 14th amendment imposes a similar limit on the power of state governments (*Chicago B. & Q. Ry. Co. v. Chicago*, 166 U.S. 226). In England, where there is no written constitution and hence no special safeguard against governmental power, there is a strong presumption of law that when an act of parliament authorizes the compulsory acquisition of private property, it is intended that adequate compensation shall be payable. This presumption, however, has not been called into operation, since in practice parliament has invariably provided for compensation in such statutes. The question of what constitutes just and adequate compensation is determined by a variety of factors, but the most common standard in both England and the United States is the monetary equivalent of the owner's loss. (F. H. HE.; T. S. LE.)

**CONFLICT OF LAWS** (**PRIVATE INTERNATIONAL LAW**) The law of conflict of laws has to do with the resolution of problems which result from the fact that there exists in the world a multiplicity of different sets of courts and of different systems of private law. As the earth is presently organized, its surface is divided among nations that are independent of each other and that have no world government above them. Each of these nations maintains its own set of courts in complete independence of every other nation, and each nation has its own set of laws, written or unwritten.

While in such countries as France, Sweden, Peru or Japan one single system of law obtains for the whole country, diversity exists in many others, especially nations organized upon a federal pattern, such as the United States of America, or Canada or, to a minor degree, Germany, Switzerland, Mexico or the Soviet Union. The law of Illinois is not the same as that of New York, Louisiana or Indiana; that of Quebec differs from that of Ontario or Newfoundland; that of Chihuahua is not quite the same as that of

**Michoacán.** In Germany and Switzerland the systems of private law are by and large uniform, but minor differences still exist between the *Länder* or the cantons.

Even in countries whose political structure is of the unitary rather than the federal pattern, differences can be found. In the United Kingdom of Great Britain and Northern Ireland considerable differences exist between the laws of England, Scotland, the Isle of Man, the Channel Islands and Northern Ireland.

Diversity of laws also exists frequently between a country and its colonies. The laws of Mauritius or Malta, for instance, are different from any of the laws prevailing in the United Kingdom, and, while in most other British colonies the laws are more or less patterned upon the model of the common law of England, they are not always exactly the same.

Diversity of laws develops where a country is divided, such as Germany, Korea or Vietnam. Where a new country is formed, or where territory is annexed, legal unity may not be brought about at the same time. After the reannexation of Alsace-Lorraine by France in 1920, for example, German private law remained in effect there for many years; and when Poland was formed out of parts of Russia, Germany and Austria, legal uniformity was not brought about until after the end of World War II.

Diversities of law within one country may also exist on an ethnic or religious basis. Such a situation commonly existed in most countries of the near and middle east; the laws concerning matters of the family, including succession upon death, remain different in India for Hindus, Muslims, Parsees and Buddhists, and in Lebanon or Israel for Muslims, Jews and the various groups of Christians. In the United States and Canada, American Indians are in several respects subject to their own tribal laws.

Because of the spread of western civilization over the entire planet, the laws of modern nations, at least as they are concerned with relations between private individuals, present a considerable measure of uniformity. They are sufficiently different, however, to make it important to know to what situations one ought to apply the law of one country, state, region or group rather than that of another, especially when dealings are carried on between persons of different law units. This question of determining which of the world's numerous laws is the proper one to apply in a particular situation is in itself a legal question. Those rules of law by which such questions of choice of law are determined constitute a major part of that field of the law which is known as private international law or, as it is usually called in the United States, the law of conflict of laws. Other parts of this field of the law are concerned with the problem of jurisdiction—i.e., the problem of determining in what cases the courts of a particular country or state are, or are not, to go into action—and, furthermore, with the problem of stating what weight, if any, is to be given in one country or state to the judgments and other decisions of the courts or other agencies of other countries or states. In countries of the French legal tradition it is customary to regard as parts of private international law also those rules that deal with nationality and with the legal position of aliens and non-residents. In accordance with Anglo-U.S. usage, however, the present article will be limited to jurisdiction, foreign judgments and choice of law.

**Sources of Private International Law in General.**—The name private international law seems to indicate that it is a part of international law; i.e., that system of law that is superior to all sovereign states and that, at least in theory, is uniform throughout the world. This view was commonly held for many centuries, and when the name "private international law" was coined in the 19th century it was meant to signify that the supranational body of international law consisted of two parts, public and private international law. While the former would determine the proper conduct of sovereign nations toward each other in both peace and war, the latter would, in a uniform way, tell all nations in what cases their courts ought or ought not take jurisdiction, under what conditions foreign judgments were to be enforced or otherwise recognized, and in what cases the laws of one nation were to be applied rather than those of another.

Since the latter part of the 19th century, however, such a view

has been considered an ideal rather than a true description of reality. Today, it is generally recognized that each nation not only determines what its substantive law (i.e., its law of property, contracts, torts, family relations, succession, corporations, etc.) is to be, but also in what cases its courts are to have jurisdiction, under what conditions foreign judgments are to be recognized, and which country's law is to be applied in any particular case.

As on other matters, nations may, of course, conclude treaties, bilateral or multilateral, in which they assume in relations with each other the duty to deal with certain problems in an agreed way. Treaties of such a kind have been concluded between numerous states, especially among countries of Latin America and of continental Europe. The United States is a party to numerous treaties that mutually secure the right of citizens of the United States, on the one part, and of citizens of the other contracting country, on the other, freely to dispose of property owned in the territory of the country of which the owner is not a citizen, and to take such property as legatees, devisees, heirs or next of kin on the death of a citizen of the other country. A treaty providing that the citizens of each contracting country shall, in the courts of the other, be treated in their family affairs and other matters of personal status in accordance with the rules of their own law was concluded by the United States and Iran. United States treaties dealing with other problems of private international law are rare. No treaties at all have been made by the United States on enforcement and recognition of judgments or on jurisdiction of courts.

The United Kingdom and the other countries of the Commonwealth of Nations are parties to numerous treaties among each other and with other nations, concerning foreign judgments and mutual rights of owning, disposing and taking of property, but British treaties on other matters are as rare as United States treaties. Where a practical problem is to be handled, however, it is nevertheless advisable always to ascertain whether or not there is in effect a treaty by which the problem may be affected.

Even in those areas, such as France, Germany or Latin America, in which the bulk of private law is contained in codes and other statutes, the statutory provisions on private international law are fragmentary, and for large parts of the field the law must be sought in the decisions of the courts. In all countries the writings of scholars have been of considerable influence.

In the United States the creation of norms of private law belongs almost exclusively to the domain of the several states. Consequently, conflicts law, too, is by and large state law rather than federal law. While there might exist as many different bodies of U.S. private international law as there are separate states, territories and possessions of the United States, all these state and territorial laws greatly resemble each other. Differences exist, however, in many questions of detail, which are due to divergent judicial decisions or to the enactment of different statutes. In those matters which, as patents or shipping, are regulated by federal substantive law, the pertinent conflicts rules are also federal law. Federal law also obtains insofar as a matter of conflicts law is dealt with in a treaty of the United States. The power of each state freely to shape its private international law by its own statutory enactments and judicial decisions is limited in the constitution of the United States by the "full faith and credit" clause of art. iv, sec. i, and the "due process" clause of the 14th amendment, sec. i.

In spite of the loosening of the legal ties between the member nations, conflicts law in the commonwealth has preserved a remarkable measure of uniformity. Those rules of private international law that have been and are being developed by the courts and legal scholars of England constitute a common fund of all parts not only of the United Kingdom and its dependencies but also of the entire commonwealth. Divergencies have begun to develop, however, through the conclusion of treaties by the several sovereign nations of the commonwealth and by the enactment of statutes by them as well as by their self-governing dependencies. In all those commonwealth nations that are politically organized upon the federal pattern, such as Canada, Australia and India, questions arise as to whether a certain problem of conflicts law

belongs to the legislative sphere of the central government or of the states or provinces.

**Jurisdiction.**—If a person wishes to bring a civil lawsuit against another person against whom he believes he has a claim, he might conceivably bring the action in any country of the world. If, however, a citizen and resident of the United States (for example) were to sue a citizen and resident of Canada in Panamá, a judgment obtained in Panamá would be of no use to him unless the Canadian owned in Panamá property which, if he did not pay, the U.S. citizen might attach there, or if the Panaman judgment could be enforced in such other country or countries in which he happened to hold property. For this practical reason the problem of where to bring suit is thus tied up with that of the enforceability of foreign judgments. However, even if a judgment might be of practical value to the plaintiff, he might find that the courts of the country in which he wished to bring his action would not receive it. As a matter of fact, all countries of the earth have limited their jurisdiction; *i.e.*, the scope of actions that they allow their courts to handle. Countries do not wish their courts to deal with lawsuits with which they have no proper contact, which might clog the calendars of their courts, or against which it would be unfair to compel a person to enter a defense on pain of having judgment by default rendered against him. Opinions differ, however, as to when it is regarded proper for a country to hear and decide a civil lawsuit. This question is determined by each country for itself.

In composite countries, such as the United States of America, the United Kingdom, Canada, Switzerland or the U.S.S.R., rules are also necessary to determine in which of the several constituent states, provinces or other parts a civil lawsuit may be brought. In some states (for instance, the Federal Republic of Germany) this determination is made by the national law. It may be left, however, to each of the constituent states to determine for itself the scope of litigation which it will allow its courts to decide. Such, at least on general principle, is the situation in the United States, where the states' freedom of determination is limited, however, by the "due process" clause of the 14th amendment to the federal constitution, which in effect prohibits the state from exercising civil jurisdiction where it would be grossly unfair to do so. In the United Kingdom and the other countries of the commonwealth, the jurisdiction of its courts is also determined for each constituent part by its own law, but the principles of such determination do not differ widely from each other.

As a general principle, most countries or states agree that a case may be tried in their courts if both parties have consented to their jurisdiction. The plaintiff's consent simply appears from his commencing his action in the state in question; that of the defendant is presumed when, rather than objecting to the jurisdiction, he confesses judgment or begins to litigate on the merits of the controversy. Some countries, nevertheless, close their courts to a litigant whose case has no more substantial connection with them than the parties' consent. French courts, for instance, will not try a lawsuit between foreigners unless it arises out of controversy that has some real connection with France, such as the allegation of a breach of a contract to be performed in France, or a tort committed in France, or title to land situated in France. As another example, the courts of New York regard themselves as an "inconvenient forum" for suits between non-residents concerning a tort committed outside New York. With few exceptions Anglo-U.S. courts will not try controversies concerning title to, or trespass upon, land situated outside the state.

Generally, however, the problem of jurisdiction does not become acute unless the defendant objects to the case's being tried in the country or state of the plaintiff's choosing, or unless he fails to appear. Different approaches to this problem of jurisdiction are followed in the countries of the civil-law tradition and in those of the Anglo-U.S. common-law tradition. The former start from the idea that the proper place for a person to be sued is his domicile or residence. In civil-law systems, in general, a person may always be sued at his residence and must not be sued in any other place. Many exceptions to the latter principle exist, however. An adjudication of the title to a piece of land, for

instance, must be brought where the land is situated. A suit arising out of an alleged tort may be brought in the place where the tort is alleged to have been committed, and a suit based upon an alleged breach of contract may be brought in the place in which it is alleged that the alleged contract was to be performed.

Some countries, for instance Germany, allow an absent defendant to be sued in their courts if he owns within the country any property. France keeps its courts open for suits of any kind brought by a French national against a foreigner. A large number of states, including those adhering to the Anglo-U.S. common-law tradition, allow a civil suit to be commenced by the attachment of property owned within the territory, the enforcement of a default judgment obtained being limited, however, to the assets thus attached.

In their general approach to the problem of jurisdiction, the common-law countries still proceed from the long-obsolete notion that no civil suit could be commenced in any way other than by the defendant's arrest by the sheriff. Consequently, an action can still be brought in any place in which the defendant is personally served with process, even though he may be there only for a few minutes to change airplanes. In modern times it has come to be widely held, however, that personal service upon the defendant is no longer an indispensable requirement of jurisdiction and that an individual may be sued in the state of his residence, even if the summons is not personally pressed upon him. A corporation can always be sued in the state in which it has been incorporated.

In the United Kingdom and other units of the commonwealth, the court may allow the defendant to be served outside the jurisdiction in a number of special situations, especially when the suit is based upon a breach of contract performable within the jurisdiction, or upon a tort committed within the jurisdiction.

Using the "due process" clause of the 14th amendment to the U.S. constitution, which forbids the states to "deprive any person of life, liberty or property without due process of law," the supreme court has held that a state may not exercise jurisdiction against an absent defendant unless the case has such minimum contact with the state that the maintenance of the suit does not offend traditional notions of fair play and substantial justice (*United Shoe Company v. State of Washington*, 326 U.S. 310; 58 S.Ct. 154 [1945]).

It is thus required that an honest effort be made to give the defendant actual notice that a lawsuit is about to be brought against him. The mere publication of the summons in a newspaper or at the bulletin board of the court is not sufficient unless the address or identity of the defendant cannot be ascertained upon a reasonable effort.

Quite generally, states of the United States are now coming to allow their courts to exercise jurisdiction in suits arising out of a breach of contract to be performed within the state, or out of a tort, especially an automobile accident, that occurred within the state. In many states a corporation may be sued if it is simply "doing business" there, even though the suit in question is totally unconnected with the state.

In both civil- and common-law countries special rules apply for suits in which the plaintiff aims at a judgment *in rem*; *i.e.*, a judgment which, rather than adjudging a defendant indebted to pay a certain sum of money or ordering him to do, or not to do, a certain act (*e.g.*, deliver a deed to a piece of land, or refrain from using a trade-mark), produces by its own effect a change of legal situation (for instance, the foreclosure of a mortgage, the removal of a cloud on a title to land, the dissolution of a marriage, the creation of an adoptive parent-child relationship, etc.). Lawsuits aiming at the court's changing the title to a piece of land can universally be brought nowhere but in the state in which the land is situated. Actions arising out of transactions connected with shipping can generally be brought in the port in which the ship in question happens to find itself. For actions for divorce civil-law countries generally keep their courts open to their nationals even if they reside abroad.

**Foreign Judgments.**—If a creditor has obtained against his debtor a judgment for \$1,000 in Mexico or in Michigan, and he

debtor does not have sufficient property in that country or state, can he enforce it in Illinois, where the debtor owns land, keeps a bank account or owns other assets? If someone has brought and lost a lawsuit in New York, can he start it all over again in California or in Peru? If the marriage of Mr. and Mrs. Smith has been terminated by a decree of divorce of a court in Nevada, or by an act of the parliament of Canada, or by the order of a district governor in Norway, and Mr. Smith wishes to remarry in Wyoming or in South Africa, will he be given a licence? If he remarries will his new marriage be valid or does he have to go to jail as a bigamist? If a citizen of the United States residing in Wisconsin adopts a child of German parents residing in Germany and the adoption has been confirmed by a court of Wisconsin, will the child inherit on the adopter's death a piece of land situated in Indiana or an account in a bank in Germany or in Switzerland?

Unless countries have bound each other by treaty mutually to enforce their civil judgments, each country is free as to whether or not, and, if at all, under what conditions, it wishes to enforce or otherwise recognize foreign judgments. The attitudes of the several countries vary considerably in this respect, and the treatment of the enforcement of money judgments is not the same as that of the recognition of a judgment as a bar to the starting of a new suit all over again (*res judicata* effect), or the recognition of the termination of a marriage by a decree of divorce or of other changes of private legal relationships brought about by judicial act.

If a judgment for money is not promptly paid by the debtor, it is enforced by the attachment and sale of his property, the proceeds being turned over to the creditor. Such enforcement is generally the task of a public officer, such as the sheriff, who is empowered, where necessary, to break resistance with physical force. While a sheriff knows well enough the looks of a judgment of his own state, he cannot be expected, or even allowed, to go into action simply upon the basis of a paper purporting to be the judgment of a foreign state with whose judicial system, language or even script he cannot be expected to be familiar. For the protection of the citizen as well as of himself, it is indispensable that, before the sheriff or other enforcement officer goes into action, the foreign judgment be transformed into a domestic one. Some countries, such as the Netherlands or Sweden, simply limit enforcement to domestic judgments. Even if the creditor has obtained a judgment abroad, he must start regular proceedings all over again, and the only advantage the foreign judgment provides for him lies in the fact that the Dutch or Swedish court will be inclined to regard it as good, although in no way conclusive, evidence of the well-foundedness of his claim. In most other countries, however, a domestic judgment will be supplied by a domestic court without a reopening of the dispute about the merits of the creditor's claim. All the domestic court will inquire into is the regularity of the proceedings in which the foreign judgment was obtained, especially if it is a judgment by default. For this transformation of a foreign into a domestic judgment, the majority of the civil-law countries provide a kind of special proceeding (*exequatur*) which is supposed to be, but is not always, simpler and less expensive than an ordinary civil lawsuit. In the common-law countries it is necessary to bring upon the foreign judgment an action that in outward form is a regular civil lawsuit but that is, at least in the normal case, simple and speedy. In the United Kingdom and the commonwealth a simplified mode of domestication is furnished by agreements and statutes providing, in certain cases, for the simple registration in one law unit of judgments rendered in another. In the United States a similar method exists in the relations between those states that have adopted the Uniform Enforcement of Foreign Judgments act.

Where a foreign judgment is not sought to be enforced by attachment of the debtor's property or similar measures, but where its *res judicata* effect is simply raised as a defense in a domestic lawsuit, or where the question is simply that of recognition of its law-changing effects, such as the termination of a marriage by a decree of divorce, it would seem to be unnecessary to require the formal transformation of the foreign into a domestic judgment by any special proceedings. Some countries (for instance, Italy

and, to a more limited extent, France) nevertheless require such formal domestication for decrees of divorce and other judgments purporting to affect the personal status of their nationals.

In the United States the constitution (art. iv, sec. i) provides that "full faith and credit shall be given in each state to the public acts, records and judicial proceedings of every other state." Under this clause the states, and by statute the territories, are obliged mutually to enforce their money judgments and to recognize the *res judicata* and law-changing effects of their judicial acts, provided the state by which the judgment was rendered was acting within the scope of its jurisdiction as defined by the supreme court of the United States. The only other defenses that might be raised are grave irregularity of the proceedings in which the judgment was obtained and, in certain cases, lack of finality.

Where the judgment in question is that of a foreign country, a U.S. court will follow the general principles of the common law under which a foreign judgment is willingly enforced and otherwise recognized unless (1) the country by which it was rendered lacked jurisdiction according to the notions prevailing in the place where recognition is sought, or (2) the proceedings in which the judgment was obtained were tainted with fraud or were otherwise grossly unfair, or (3) the recognition or enforcement of the foreign judgment would seriously interfere with an important public policy of the state where recognition or enforcement is sought. In addition to these requirements, most civil-law countries (except, of course, those few in which foreign judgments as such are not enforced at all) also demand that reciprocity with the country whose judgment is sought be recognized. In many civil-law countries a foreign judgment concerning a matter of personal status of a citizen also will not be recognized unless the foreign court has observed certain rules of the substantive law of the country where recognition is sought.

Nowhere will a foreign judgment be enforced or recognized unless the state by which it was rendered had jurisdiction to do so under the notions obtaining where recognition is sought. These limits are sometimes wider, however, than those which a country will concede to others for the exercise of their jurisdictions. While France, for instance, holds its courts open for all suits of a Frenchman against a foreigner, a U.S. or English court will not recognize a default judgment obtained in such an action unless the defendant was served with process in France, or was a resident of France or had some other contact with that country which justifies his being sued in France.

In matters affecting personal status, especially divorce, civil-law countries generally recognize judgments rendered by the courts of the country of which the parties are nationals. Under the common law of England a decree of divorce will not be recognized unless it was rendered by the state of the domicile of the husband. After World War II, however, there were enacted in some parts of the commonwealth statutes under which a wife living separately from her husband might also sue for divorce in the state of her residence, and a decree thus obtained is likely to be recognized in the other parts of the commonwealth.

In the United States the supreme court has determined that a divorce granted in one state must be recognized in all others if the state by which it was granted was the state of the true residence of the plaintiff (*Williams v. North Carolina*, 317 U.S. 287; 63 S.Ct. 207 [1943]) or if the defendant actually participated in the proceedings without contesting the plaintiff's allegation of residence (*Sherrer v. Sherrer*, 334 U.S. 343; 68 S.Ct. 1087 [1948]; *Johnson v. Muelberger*, 340 U.S. 581; 71 S.Ct. 581 [1951]). Since the courts of certain states (for instance, Nevada) tend to take as true the unproved and uncontested allegations of the plaintiff as to cruelty or other grounds for divorce, the supreme court of the United States has thus rendered it possible for the residents of all states of the union to obtain a divorce by mutual consent, although that kind of divorce is not provided in the official law of any of the states. Where a divorce has been obtained by one spouse without the co-operation of the other, recognition may still be denied upon the ground that the state by which it was granted was not that of the true residence of the plaintiff (*i.e.*, the state in which he in-

results of these efforts can be found in the works listed in the bibliography. Here no more can be done than state some over-all approaches; these must not be regarded, however, as rules of immediate applicability.

As to problems concerning an individual's personal status (e.g., whether or not he has capacity to marry; what are the mutual rights between a husband and his wife, or between parent and child; or whether or not one individual is the legitimate child of another), it is universally held that they are to be decided under the law of that unit to which the individual in question "belongs." Under the view prevailing in most, but not all, civil-law countries, a person "belongs" to that country of which he is a national. This approach is of little help where a person is a national of a country, such as the United Kingdom or the United States, that does not have a uniform system of private law. In the common-law countries "belonging" is thus expressed in terms of either "domicile" (United Kingdom) or "residence" (United States). Difficult choices or combinations have to be worked out for cases involving relations between persons "belonging" to different law units. As to the formalities required for the conclusion of a marriage, observance of those of the place of celebration is widely held sufficient and in many laws is even required.

Legal problems concerning title to land are universally held to be determinable under the law of the place where the land is situated. The application of the *situs* principle to movables meets with difficulties because of their movability. In common-law countries, problems of succession to property upon death are also referred to the law of the *situs* insofar as land is concerned. In civil-law countries a tendency exists, however, to decide such questions under the law of the country of which the decedent was a national. That law is also applied in civil-law countries to problems concerning succession to movables, while common-law countries in this respect look to the law of the decedent's domicile or residence. Special rules apply, however, to the making of a will. As to the formalities required, it is widely held to be sufficient that the testator has observed those that are stated in the law of the place where he executed the instrument. As to interpretation and construction of a last will, detailed choice-of-law rules are necessary to take care of the great variety of possible situations.

Problems of the law of torts are almost universally referred to the law of the place where the tort is alleged to have been committed. But where is that place when a person acting in one state injures a person in another state, as, for instance, when A, canning spoiled food in state Z, injures the health of B, who bought the can in Y, ate the contents in X, fell sick in W and died in V; or where a defamatory speech is broadcast over a powerful transmitter and heard over a wide area of different states?

The greatest difficulties have arisen in the field of contract. Many courts and writers, especially in the United States, have held that problems of the law of contract are generally to be decided under the law of the place where the contract was made. Under a refinement of this theory, problems concerning performance are to be decided under the law of the place where the contract was to be performed. But where is a contract made when it was concluded by the exchange of letters between San Francisco and Chicago, or New York and Paris? Where is the contract of sale to be performed when the seller has to obtain the goods in New Orleans and ship them from New York to Amsterdam, and the buyer, a business firm in Oslo, has to pay the price at a bank in London? Furthermore, what intrinsic connection with the parties' relationship does the place of contracting have at all, if, as frequently happens, the contract was made at a place at which quite accidentally the parties' minds met. Should Utah law really be applied to a contract concluded by a New Yorker and a Californian while they were flying over Utah in an airplane?

The view most widely followed by the courts of both civil-law and common-law countries is that problems concerning an alleged contract are to be decided in accordance with that law which the parties expressly agreed to be applicable, or which is recognizably that law upon the basis of which the parties negotiated and made their contract. Theoretical objections to this practical view still

carry some weight, especially in the United States. Where no particular law can be discovered as the one upon the basis of which the parties transacted their business, detailed differentiations must be made depending on the kind of contract in question (sale, insurance, transportation, contract for services, suretyship, etc.) and on the particular problem to be decided. Although the field of contract is the most important for interstate and international trade, it is the one beset with the most uncertainties as to choice of law. Fortunately, the substantive laws do not widely differ from each other, and business has learned to avoid many of the difficulties through resorting to arbitration and appropriate drafting. Through skilful draftsmanship the experienced international lawyer can prevent many of the difficulties which can so easily arise under private international law.

**CONFORMAL REPRESENTATION:** see ANALYSIS, COMPLEX.

**CONFORMATIONAL ANALYSIS.** Conformational analysis may be described as the correlation of the preferred shapes or conformations of organic molecules with their chemical and physical properties. Frequently it is possible to assume a preferred conformation from the molecule and thus to deduce something of its chemical and physical properties.

The true nature of an organic molecule is defined only when its constitution, its configuration and its conformation are known. The first indicates the order in which the constituent atoms are joined together. The question of the configuration of a molecule arises only when there is a centre of asymmetry present, such as a saturated carbon atom attached to four different groups or a double bond asymmetrically substituted by two or more different groups. By assuming free rotation about all single bonds and restricted rotation about double bonds J. H. van't Hoff in 1874 deduced that the number of isomers (see ISOMERISM) arising from the presence of  $n$  centres of asymmetry would be  $2^n$ . Much experience has proven the correctness of this theory. The number  $2^n$  represents, in principle, stable molecular entities having the same constitution but differing in configuration. Each different configuration is, of course, nonsuperposable on any other.

Evidence that the assumption of free rotation about carbon-carbon single bonds required modification first appeared when it was shown that certain 2:2':6:6'-tetrasubstituted diphenyls (I; X and Y = substituents) could be resolved into stable optical isomers. J. Kenner and E. E. Turner postulated in 1926 that the asymmetry was produced by restricted rotation about the single bond (a) in I due to the bulkiness of the substituents X and Y.

In 1936 the methods of chemical physics showed that restriction of rotation about single bonds was common to all organic compounds and that certain arrangements of bonded atoms in space were preferred. It is convenient to use the word conformation (W. N. Haworth, 1929) to describe an arrangement in space of the atoms of a molecule of defined configuration which is not superposable upon any other. From this definition it follows that an infinite number of conformations are possible even for as simple a molecule as ethane,  $\text{CH}_3\text{—CH}_3$ . However, only two extreme conformations, shown in II and III looking down the carbon-carbon axis, need be discussed. In II, the staggered conformation, the hydrogen atoms are as far away from each other as possible and the energy of the system is at a minimum, whereas in III the

hydrogen atoms are as close as possible and the energy is at a maximum. The energies of the infinite number of conformations which lie between these two extremes are also intermediate. Thus ethane at normal temperatures will exist mainly in the staggered low-energy conformation but as the temperature of the gas is raised, i.e., energy is introduced into the system, then an increasing proportion of it will adopt conformations of higher energy.

In *n*-butane ( $\text{CH}_3\text{—CH}_2\text{—CH}_2\text{—CH}_3$ ), there are four limiting conformations shown in IV, V, VI and VII. That of lowest en-

ergy is IV in which the methyl groups are as far apart as possible, next comes the staggered arrangement V in which the methyls are fairly close together. Of the high-energy arrangements VII, in which the methyls are opposed, is less stable than VI, in which methyl is opposed to a hydrogen. Thus it can be seen that, in general, the preferred conformation is that in which the largest groups are farthest apart; this is due to the interaction of the non-bonded atoms whose electron atmospheres repel each other.

The barriers to free rotation in ethane, *n*-butane and related molecules are only of the order of a few kilogram calories per mole. Although this is sufficient to ensure that the molecules exist in the preferred staggered conformations it is far too small to allow the separation of stable isomers.

In 1890 H. Sachse pointed out that, if the valency angles of carbon were retained at the natural tetrahedral angle of  $109^\circ 28'$ ,

then cyclohexane (VIII) could exist in two conformations free of angle strain. These are usually designated the chair (IX) and boat (X) conformations. In IX all the bonds are staggered with

respect to their neighbours, whereas in X there are six pairs of opposed interactions. Thus it would be expected that the chair conformation (IX) would be the more stable. This has, in fact, been established experimentally beyond question, a direct physical proof being provided by the electron diffraction work of O. Hassel (1948) and supported by statistical mechanical studies (K. S. Pitzer, 1948).

In IX it can be seen that two geometrically distinct types of carbon-hydrogen bond are present. Six of the bonds are parallel to the threefold axis of symmetry of the ring and are called axial bonds (D. H. R. Barton, Hassel, Pitzer and V. Prelog, 1954).

The other six carbon-hydrogen bonds, placed in an equatorial belt around the molecule, are called equatorial (e). The conformation IX can be inverted to the alternative, but in every way

equivalent, chair (XI) simply by movement of all carbon atoms through a plane. In this process an axial hydrogen—say ( $\pi$ ) in IX—becomes equatorial ( $[\pi]$  in XI) and vice versa. The energy to effect this process is only a few kilogram calories and therefore it is not possible to isolate boat and chair conformational isomers in cyclohexane or its derivatives.

Monosubstituted cyclohexanes can, in principle, have the substituent in the axial or equatorial arrangement, the two alternatives being different conformations of the molecule. In fact, it is the equatorial orientation which is favoured except in exceptional circumstances. In the equatorial conformation (XII) the substituent X is close enough in space to interact only with the two equatorial and two axial hydrogens on the methylene groups proximate to the C—X bond; i.e., four 1:2 H:X interactions. Note that the geometry of the molecule is such that all 1:2 H:X interactions are identical. Similarly in the axial conformer (XIII) the substituent interacts with the two equatorial hydrogens on the

be in opposition to placing the maximum number of substituents in equatorial orientations.

In compounds of the decalin series two cyclohexane rings are fused together. By arguments such as those discussed above it can be predicted that cis-decalin (XIV) is less stable than the trans isomer (XV). In XIV conversion of equatorial to axial substituents is again possible by inverting the conformation. However, in XV this is impossible since the bonds, a and a', are equatorial with respect to the other ring and to make them axial would give rise to an impossibly strained ring. In the case of XIV these corresponding bonds are axial and equatorial respectively and the inversion of conformation would merely change them to equatorial and axial respectively. Thus in polycyclic systems where one or more rings are trans-fused the axial and equatorial isomers are not interconvertible. It is in these cases where the rigidity of the molecule prevents there being any ambiguity about the orientation of substituents that conformational analysis has made its most important contributions. The fundamental tenet of conformational analysis is that the preferred conformation of a molecule can be related to its physical and chemical properties. This was first shown in polycyclic systems in 1950 by Barton, mainly with examples from the steroid field.

The most important applications of the above theory may be divided into two classes—first, molecular properties which may be equated directly to a preferred conformation, and, second, molecular properties resulting from the interplay of conformational preferences and the geometrical requirements of the transition states of organic reactions. In the first class may be grouped such properties as specific bands in the infrared or ultraviolet spectrum of a compound. For example in  $\alpha$ -halogenocyclohexanones if the halogen is equatorial, the infrared maximum of the carbonyl group is displaced but if the halogen is axial the frequency remains unchanged. In the ultraviolet spectrum the opposite holds true; thus in an axially substituted  $\alpha$ -haloketone there is a displacement of the ultraviolet maximum but not in the corresponding equatorial compound.

Direct correlations are also seen between chemical properties controlled by steric compression such as acylation and ester hydrolysis rates and preferred conformations. Since it is known that the greater stability of equatorial over axial alcohols is due to steric overcrowding in the latter it would be expected that acylation of a hydroxyl in the equatorial position would be less hindered and thus proceed more rapidly than in the case of the axial analogue. Similarly it would be predicted that hydrolysis of equatorial esters would occur more rapidly than in the case of the corresponding axial compounds. This has been amply proven in the case of various steroidal alcohols where the axial and equatorial pairs were examined with hydroxyl groups at the positions numbered in XVI. That the equatorial alcohol is more stable

adjacent carbon atoms and with the two axial hydrogens on the next but one carbon atoms; i.e., two 1:2 H:X and two 1:3 H:X interactions. When H:H interactions are considered it is found from models that the 1:2 hydrogens are the same distance apart as the 1:3 axial hydrogens and thus have the same repulsive energy, but if any substituent larger than H is introduced then the 1:3 axial distance is smaller than the 1:2 distance which will therefore have a smaller energy of interaction.

So it may be said that, in general, substituted cyclohexanes tend to exist mainly in the conformation in which the largest group is in the equatorial position or, if more than two substituents are present, with the largest number of groups in the equatorial positions. This general rule does not always hold when the substituents have appreciable dipole moments for, in these cases, the dipoles tend to be oriented in opposite directions and this may

than the axial has also been demonstrated in these steroidal alcohols, mainly by reduction of the corresponding ketone with sodium and an alcohol to a mixture of the axial and equatorial isomers. In all cases the equatorial alcohol preponderates and must be the more stable since reduction under these conditions gives an approximation to the equilibrium mixture.

The greater stability of the equatorial over the corresponding axial substituent has been demonstrated for numerous groups in various environments, especially in rigid fused ring systems such as steroids and triterpenes where the configuration of a substituent defines its conformation.

This ability to define unambiguously the conformation of a compound is particularly important in the second way in which conformational analysis is applied; *i.e.*, the analysis of reaction mechanisms. Although flexible compounds such as substituted cyclohexanes usually exist in one preferred conformation this does not mean that they have to react in this form. For example, cyclohexylbromide exists mainly as the equatorial conformer but it is almost certain that when it is dehydrobrominated to cyclohexene the form which reacts is the axial isomer. It is thus in rigid systems where the conformation can be rigidly defined that conformational analysis can be applied most fruitfully.

The transition state of lowest energy for an ionic bimolecular elimination requires that the four centres involved be in one plane. This requirement is fulfilled (the two joined carbon atoms with their attached substituents) by trans-1:2-diaxial substituents in conformationally rigid cyclohexane systems but not by trans-1:2-diequatorially substituted compounds or by either of the cis (equatorial axial) isomers.

For example, 5 $\alpha$ :6 $\beta$ -dibromocholestane (represented in partial formulation by XVII) has two axial bromine atoms. It is debro-

XVII

minated by iodide ion much faster than its 5 $\beta$ :6 $\alpha$ -isomer (XVIII) where both bromines are equatorial. As a corollary to this rule

XVIII

it has also been established that electrophilic addition to double bonds gives the trans diaxial product; in most cases this is the thermodynamically less stable one. Thus cholest-2-ene (XIX) gives mainly the diaxial 2 $\beta$ :3 $\alpha$ -dibromocholestane (XX). Similarly, it has been shown that epoxides, such as cholest-2-ene  $\alpha$ -epoxide (XXI), give the diaxial product (*e.g.*, XXII) on ring opening although they could conceivably give the more stable diequatorial products; *e.g.*, XXIII. Conversely it has been shown that the diaxial halohydrins on treatment with alkali reform the epoxide ring much more rapidly than do the corresponding diequatorial compounds.

Although conformational analysis can be more favourably ap-

XIX

XX

plied to rigid systems it has also been widely and fruitfully used in aliphatic and heterocyclic systems, and also in large and small ring compounds though the latter do not have the symmetrical perturbation of the cyclohexane ring. The substitution of hetero atoms such as nitrogen and oxygen for one or more of the carbon atoms of a cyclohexane ring causes only a slight distortion of chair

XXIII

XXI

XXII

conformation. In consequence the generalizations that have been found pertinent in cyclohexane chemistry can be carried over in main part to heterocyclic analogues. Thus tetrahydropyran

XXIV

(XXIV) may be represented by the conformation XXV. Many of the compounds of carbohydrate chemistry contain the tetrahydropyran ring and it has been shown that the chair conformation

XXV

(XXV) is adopted wherever possible.

Although conformational analysis is mainly a qualitative interpretation of observations, quantitative studies are beginning to be of interest. It was first shown by S. Winstein in 1955 that the rate constant  $k$  for a reaction of a monosubstituted cyclohexane can be expressed as

$$k = k_a N_a + k_e N_e$$

where  $k_a$  is the rate constant for a pure axial conformer,  $k_e$  the constant for the equatorial conformer and  $N_a$  and  $N_e$  represent the mole fractions of axial and equatorial conformers present ( $N_a + N_e = 1$ ). Winstein and also E. L. Eliel initiated studies on the validity of this equation.

This quantitative approach assumes, of course, that the reactivity of the molecule can be defined in terms of 1:2- and 1:3- interactions (*see above*). The rates of certain condensation reactions of steroid and triterpenoid ketones have been investigated (Barton, 1955 and later) keeping the 1:2- and 1:3- interactions constant. It is found that the rates of reaction vary in a remarkable manner for remotely placed substituents. This has been regarded as due to conformational transmission; *i.e.*, the transmission of the effects from one ring to another through the whole

molecule. See also ISOMERISM; STEREOCHEMISTRY: *Conformational Analysis*.

**CONFUCIANISM** is, and has been for more than 2,000 years, the dominant philosophical system in China and the controlling factor in many aspects of Chinese culture. Understanding of it is basic to any understanding of traditional Chinese civilization.

### HISTORY

The Confucian school owes its name to Confucius (551–479 B.C.), the most revered person in Chinese history. In Chinese it is called *Ju* ("weaklings"), referring to a group of specialists on the six arts of ceremonies, music, archery, charioteering, history and numbers, of whom Confucius was one. Because of his strong sense of social responsibility and dedication to social and political reforms, however, Confucius transformed the *Ju* of the weak into the *Ju* of the strong. He and his followers traveled from one state to another trying to persuade the feudal lords to carry out social reforms. Though they had no rigid program they did have what they called the Way, or the "one thread," that runs through Confucius' teachings. This is the Way of *jen* ("humanity" or "love"). They wanted the individual to be a "superior man"—that is, a man of perfect virtue, who, wishing to establish his own character, also helps others to establish theirs. They wanted the family to be harmonious, the state to be well ordered and the world to be at peace. In short, they taught moral self-cultivation and social and political order through moral efforts. They were not only teachers, however, but people primarily devoted to reforms.

Confucius' followers, though they adhered to his fundamental doctrines, were by no means unanimous in their thought. In the 5th century B.C. two clearly divergent tendencies developed. One, represented by the *Great Learning* (*Ta-hsüeh*), was social and political in character. This short classic, the text of which has been attributed to Confucius and its commentary to his pupil Tseng-tzu (505–436 B.C.), aims at "manifesting one's clear character, loving the people, and abiding in the highest good." This is to be accomplished through the eight steps of (1) investigation of things, (2) extension of knowledge, (3) sincerity of the will, (4) rectifying the mind, (5) cultivating the personal life, (6) regulating the family, (7) ordering the state and (8) bringing peace to the world. The other tendency, represented by the *Doctrine of the Mean* (*Chung-yung*), written probably by Confucius' grandson Tzu Ssu (483–402 B.C.), was religious and metaphysical, interpreting Confucius' doctrine of the mean to be central harmony—that is, the full realization of the self through the harmony of the emotions, and the development and operation of all things in their harmonious relationships. Underlying all this is sincerity, which, as the Way of all existence, is absolute, intelligent and indestructible. Only those who are absolutely sincere can develop fully their own natures, the natures of other people, the nature of things and finally partake in the creative work of Heaven and Earth.

The *Great Learning* did not exercise much influence until the 11th century, but the *Doctrine of the Mean* seems to have been influential almost from the beginning. Certainly Mencius (*q.v.*) elaborated on the idea of sincerity and carried the doctrine of human nature to new heights. To him, human nature is originally good, and therefore the way to achieve perfection is to "nourish the mind" and "fully develop one's nature." In this respect he was diametrically opposed by Hsün-tzu (*q.v.*), who insisted that human nature is evil and needs to be disciplined through ceremonies and music, religious rites, law and "rectification of names." Mencius understood Heaven to be the highest spiritual and mystical power, but Hsün-tzu took it to mean nature. The idealistic Mencius and the naturalistic Hsün-tzu, who have been compared with Plato and Aristotle, thus represented another twofold development in ancient Confucianism. Nevertheless, their aims were the same as those of Confucius: a perfect, moral individual and a harmonious social order. Like Confucius, too, they dedicated them-

selves to political reforms; Mencius traveled and advised kings, and Hsün-tzu was once a magistrate. Generally speaking, Mencius was closer to Confucius in both thought and action; Hsün-tzu's naturalism brought him close to Taoism, and his emphasis on discipline helped to prepare some of his pupils to become leaders of the Legalist school.

Mencius and Hsün-tzu, though they were the two most outstanding Confucianists in ancient China, were not the only prominent philosophers. In fact, the Confucian school was but one of the so-called "100 schools," and probably not the most influential one. It was attacked by Taoists, Moists (or Mohists) and later by Legalists. Obviously in its stress on activity and reform and on ceremonies and government it came into collision with the quietistic Taoists, who believed in "taking no action" and leaving things alone. Earlier Taoist hermits had chided Confucius, and Chuang-tzu (d. c. 300 B.C.) made him a favourite object of ridicule. Mo Ti (470?–391 B.C.), founder of Moism, accused Confucius of insincerity. The Moists, moreover, preached a radical doctrine of universal love that would have destroyed the foundation of Confucian ethics, so that Mencius had to take it upon himself to refute Moism and defend his school lest the light of Confucianism be extinguished. To Confucius and his followers *jen*, though ultimately it meant love for all, in actual practice must begin with love for one's own parents; *jen* must grow from filial piety as a tree must grow from its roots.

In opposition to this teaching of love with distinctions, the Moists vigorously advocated love without any gradation or discrimination. Mencius' bitterness clearly indicates that Confucianism was on the defensive: "Mo's doctrine of universal love means that no peculiar affection is due a father. To acknowledge no father is to be a beast."

Later Confucianism came into strong conflict with the Legalists also. Confucianists had always condemned force as a way of life and profit or advantage as standards of value. In this they stood in direct opposition to the Legalists, whose goal was power and control, and as the Legalists grew in strength, the standing of Confucianism correspondingly declined. Eventually the Legalists helped the state of Ch'in to defeat its rivals, united China as an empire and established a dictatorship from 221 to 206 B.C.

**Confucianism as the State Cult.**—In order to control thought, the Ch'in in 213 B.C. burned all books except those in the imperial archives and works on medicine, divination and agriculture. The Confucian school, along with others, was almost wiped out, leaving the Legalists the sole arbiters of ideas. But the Ch'in dictatorship lasted only 14 years. The next dynasty, the Han (206 [202] B.C.–A.D. 220 [221]), though it at first favoured Legalism and Taoism, finally turned to Confucianism. One of the reasons for this change was that the ancient classics, copies of which had been hidden to escape the burning, had reappeared; since the Confucianists were authorities on the classics, their prestige was high. Furthermore, as experts on ceremonial, they instituted ceremonies that greatly pleased the Han emperors. In addition, the emperors found pleasing Tung Chung-shu's modifications of Confucian thought, which led to glorification of the ruler. Tung incorporated into Confucianism the Yin Yang philosophy, which considers everything as the product of the interaction of the negative cosmic force, *yin*, and the positive cosmic force, *yang*. The result was Tung's famous theory of correspondence between nature and man, in which every human event has its counterpart in nature and vice versa. In this scheme of things the ruler corresponds to Heaven, both being *yang*; the emperor, the father and the husband became the "standard" of the *yin* forces, the minister, the son and the wife, respectively.

In 136 B.C. Confucianism was proclaimed the state doctrine, and in 124 a national university was founded with departments corresponding to the classics. Soon these became required texts in all education, and eventually government officials were selected on the basis of their knowledge of them. Confucianism had achieved supremacy and had become a state cult.

This cult is not to be understood in the religious sense, for Confucianism was not regarded as a religion. Though it promoted the traditional worship of Heaven, the sacred mountains and rivers, and

ancestors, its supremacy lay in the secular realm. The Confucianists instituted rites and created musical systems for the Han; they formulated social and moral concepts; they controlled education; with some exceptions they monopolized the government; they wrote histories and interpreted history in their own light. Their domination in these fields was to last until the 20th century. In the spheres of metaphysics and religion, however, Confucianism was overshadowed by Taoism and Buddhism up to the advent of Neo-Confucianism in the 11th century.

For centuries after Tung Chung-shu there was no significant development in Confucian philosophy. Confucian talents and efforts were directed chiefly to textual criticism and literature, in which remarkable achievements were made. In the field of philosophy only two developments deserve mention. One was a crude cosmology arrived at by borrowing ideas from Taoism and from the Yin Yang and Five Elements schools. Briefly speaking, the universe is conceived to have originated from a prime force called One or Origination. This force expresses itself in material force (*ch'i*), both positively as the *yang* and negatively as the *yin* and also through the five elements or agents of metal, wood, water, fire and earth. The material force that is pure forms the heavenly bodies, while the material force that is turbid forms the earthly bodies. Rocks, grass and plants, insects and animals, and finally man emerged in succession in the ascending scale of balance of the elements and harmony of *yin* and *yang*. Man is the most intelligent because his endowment by nature is the best and most harmonious. This cosmology was not refined further because the Confucianists were satisfied with it: it was sufficient to support their ethical and political doctrines, for man and nature obey the same laws.

The other philosophical development was the growing concept of human nature. Many theories were offered—that man's nature is good, is evil, is neutral, is both good and evil, is good in some people but evil in others, or is divided into three grades of good nature, neutral nature and evil nature. The general conclusion was that nature is good, thus reaffirming Mencius; evil was explained as a result of imbalance of the emotions.

These developments serve to remind us of the intense moralism and humanism of Confucianism. Philosophically, however, they are trivial in comparison with Taoist and Buddhist thought of the 3rd and 4th centuries. At that time the Neo-Taoists evolved a new metaphysics, conceiving reality as "originally undifferentiated" or "nonbeing." Later, from the 4th to the 8th century, several Buddhist philosophical schools were introduced from India, and Chinese Buddhists developed a metaphysics and epistemology at a level never before reached in the history of Chinese thought. In the field of art, too, the Taoists developed landscape painting and the Buddhists developed sculpture and religious painting, while Confucianism contributed little save in poetry and literature, although many painters were Confucianists. In religion, both in popular practice and in thought, first the Taoists and then the Buddhists were the organizers, promoters and leaders. The Confucianists were ignorant of Buddhist literature and ideas and had little contact even with Buddhist scholars. They considered popular Taoist and Buddhist religious practice as befitting only the ignorant, condemned the belief in transmigration as nonsense and the acceptance of heavens and hells as motivated by selfishness and fear.

In spite of Confucian control of government and society, both Taoism and Buddhism, especially the latter, continued to grow. One factor contributing to this was their support of such Confucian institutions as ancestor worship; another was their ability to influence the government. In time they attracted many adherents and controlled much land, threatening the national economy and the security of Confucianism as the state cult. Eventually the greatest Confucianist of the T'ang period (618-906), Han Yü, issued a call to "make the Buddhists and Taoists human beings again and burn their books." Han was fighting to defend the Confucian Way—which was, as he put it, "to sustain the life of one another" and "to order the state and regulate the family"—against the Buddhist and Taoist Way, which was the Way of "having no activity and of 'silence and annihilation.'" Eventually, during the 9th

century, Buddhism was persecuted, and with its decline other organized religions declined also. But by this time Taoist and Buddhist metaphysics and epistemology had penetrated Confucianism and changed it. The result was Neo-Confucianism.

**Neo-Confucianism.**—By the 11th century Confucianists had become tired of textual criticism and flowery compositions. Though they refused to accept the "strange doctrines" of Taoism and Buddhism, they could not resist their attraction. Thus some of the tenets of the other two systems came to be incorporated into Confucianism, and in the process Confucianism was made new.

This new movement, called Neo-Confucianism in the west, is called the School of Li ("principle," "reason") in Chinese. Essentially the Neo-Confucianists of the Sung period put Confucian moral and social teachings on a new metaphysical foundation. They replaced the Buddhist void, which was to them vague and negative, with Principle (*li*), which they considered concrete and positive. Principle is the Great Ultimate of existence, absolute, eternal, the form according to which all things have their being and the source and totality of goodness and truth. It operates through the material force (*ch'i*) that gives individual things their individual form and character through the interaction of *yin* and *yang*. Man is the greatest embodiment of Principle; at its best, human nature is identical with Principle. The traditional Confucian doctrine that human nature is good was now provided with a metaphysical foundation.

Among several Neo-Confucian schools, two, Ch'eng-Chu rationalism (named after Ch'eng Yi-ch'uan, also called Ch'eng Yi, and Chu Hsi) and Lu-Wang idealism (named after Lu Chiu-yüan and Wang Yang-ming) were most prominent. Their differences are best shown by those between Chu Hsi and Lu Chiu-yüan (qq.v.). To Chu Hsi, Principle and material force are sharply different, to Lu, they are one. To Chu Hsi the mind is the function of Principle, but to Lu it is Principle. Principle is to be discovered, for Chu Hsi, in things; for Lu, in the mind. As the way of life, Chu advocated "following the path of inquiry and study," while Lu advocated "honouring the moral nature." Both of them bitterly attacked Buddhism, but the Neo-Confucian emphasis on Principle and on the mind betray direct borrowing from it, for Chinese Buddhist philosophers had for centuries been building their philosophy on these two foundation stones.

Chu's rationalistic Neo-Confucianism has dominated Chinese thought ever since its inception. Gradually the school became rigid and dogmatic, and opposition arose, especially in the person of Wang Yang-ming, whose idealistic Neo-Confucianism was the strongest philosophical current in the Ming dynasty (1368-1644). His doctrine of innate knowledge of the good and of innate ability to do good, as well as his doctrine of unity of knowledge and action, gave Confucianism a fresh vigour, but eventually overemphasis on the mind led his school to become too Buddhist for other Neo-Confucianists, and his later followers, in the name of free will, became politically and morally irresponsible. Reaction was inevitable. Neo-Confucianists of the early Ch'ing period (1644-1912) opposed both Chu Hsi's rationalism and Wang's idealism and blamed the latter's disciples for the Manchu conquest of China. Influenced by western knowledge introduced by Jesuit priests, they emphasized practical application of knowledge and the use of the scientific method. They criticized Chu Hsi's twofold division of Principle and human desire as well as Wang's identification of Principle with the mind. They stressed the primary importance of learning through practice and the actual demonstration of moral values. Outstanding thinkers such as Yen Yüan and Tai Tung-yüan, also called Tai Chen (qq.v.), were all strong in this critical and empirical spirit. But this scientific temper was expressed almost exclusively in book study, especially higher criticism and historical research.

## DOCTRINES AND INSTITUTIONS

These three phases—rationalism, idealism and the critical and empirical trend—indicate that Confucianism after the end of the 1st millennium A.D. was by no means static. Two aspects, however, characterize all these new waves: First, the developments took

place within the Confucian tradition, with fewer and fewer fresh ideas from outside; second, while philosophical theories superseded one another, the major concepts of ethical value and social institutions remained faithful to the original ideas of Confucius. These doctrines and institutions are summarized below.

**Philosophical.**—As remarked above, controversy surrounded the problem of Principle and material force. In general, the dualism of the Ch'eng-Chu rationalistic school was dominant from the 12th through the 15th century. In the 16th century it was challenged and almost replaced by the idealistic school of Wang Yang-ming, which insisted that Principle and material force were one. As Wang's school declined in the early 17th century, the Ch'eng-Chu school regained its strength. Thereafter, as thinkers reacted against both the rationalistic and idealistic tendencies, more and more importance came to be attached to material force, regarded as the primary element in existence. No doubt the increasing emphasis on facts and action ran against speculation on either Principle or the mind.

Another problem in which controversy was carried on for several hundred years was that of "investigation [*ko*] of things." In large measure divergence on this issue paralleled that on the question of Principle itself. The Ch'eng-Chu school interpreted *ko* to mean investigating Principle in all things in which it inheres, either inductively or deductively. Wang Yang-ming and his followers, on the other hand, took *ko* to mean rectifying—that is, rectifying the incorrectness of the mind, on the premise that Principle is identical with the mind. The majority of Neo-Confucianists, however, including those who regarded material force rather than Principle as the ultimate element, favoured the objective study of things. It is this tradition of rationalism that has distinguished Confucianism most clearly from the intuitive approach of Buddhism and Taoism.

In ethics the Neo-Confucianists continued the classical doctrine that human nature is good and that the greatest moral value is *jen* ("humanity"). But they took important steps forward. Instead of explaining evil in terms of feelings, they ascribed it to an imbalance in the endowment of physical nature. Superficially, this theory is as fatalistic as that associating evil with feelings, since both feelings and physical nature are natural endowments. The great difference with the Neo-Confucianists is that through moral efforts man can transform his physical nature and restore its balance. Once this is done, the originally good nature can be fully developed, and the old Confucian saying that all people can become sages like the legendary Yao and Shun is once more reaffirmed.

As to the doctrine of *jen*, the central basis of Confucian moral philosophy, there was a long course of evolution, during which *jen* was extended to include the entire universe, in addition to the original Confucian meaning of a perfect individual and an ordered society. Before Confucius' time *jen* was understood as kindness of rulers to their subjects. It was gradually broadened to mean benevolence, still a particular virtue but no longer restricted to rulers. Confucius changed it to connote perfect virtue, which includes all particular virtues and applies to all men. Mencius and the *Doctrine of the Mean* went on to say that "*Jen* is *jen*"—that is, *jen* is the distinguishing characteristic of man. During the Han period, it was generally interpreted as love, and Han Yü in the T'ang period stressed it as love for all mankind. Under the influence of Buddhism, which extended its compassion to include not only all men but all things as well, the Neo-Confucianists of the Sung and Ming dynasties similarly extended *jen* to mean "forming one body with Heaven, Earth and all things." This thought was common to both the rationalistic Ch'eng-Chu and the idealistic Lu-Wang schools. Some Sung Neo-Confucianists, however, took *jen* to be a state of consciousness. Chu Hsi called it "the character of the mind and the principle of love," and Wang Yang-ming equated it with the "clear character" of innate knowledge. All these were too quietistic and too Buddhist for the 17th- and 18th-century Neo-Confucianists, who went back to an early Han commentary on an ancient classic that defines *jen* as "people living together." The new emphasis thus was on the social and active aspects of *jen*. All Neo-Confucianists agreed, however,

that *jen* or humanity is a moral quality imparted by Heaven, and since the "great characteristic" of Heaven and Earth is to produce and to reproduce, so *jen* is characterized by production and reproduction; that is to say, it is life-affirming and life-giving, not only active but creative. Under the influence of western science in the late 19th and early 20th centuries, modern Confucianists likened *jen* to electricity and ether, an all-pervasive substance and a dynamic force.

Thus, in a long series of developments, the philosophical basis of Confucianism acquired new meanings from time to time. But all Confucianists, ancient and modern, assert in unison that *jen* is the sum total of all virtues and that its demonstration must begin with love for one's own parents.

**Ethical.**—The man of *jen* is none other than the Confucian "superior man," a man of humanity, wisdom and courage, the three "universal virtues" of Confucius and his followers. Mencius taught humanity, righteousness, propriety and wisdom as the "four beginnings" of the moral life. Later Confucianists added faithfulness and called them the "five constant virtues." They also regarded propriety, righteousness, a sense of integrity and a sense of shame as the "four bonds" for the nation. All these are norms for the thoughts, words and deeds of the superior man. He is devoted to righteousness instead of to profit, and he worries about the moral law rather than about poverty.

The starting point of all these, however, is filial piety, the root of all moral life because parents give their children their lives, their care and their bringing up; because the relation between parents and children is the first relationship and a natural one; and, most important of all, because no one can be good to anyone else unless he is good to his parents.

A number of institutions have grown up around this central concept. As expressions of genuine love for parents, children are obliged to serve, support and obey them. After the parents' death they are to be honoured in regular ancestral rites and their graves are to be well taken care of. The teaching of obedience may suggest submission of the son to the father, but in fact obedience should be neither blind nor unconditional, and a son has a moral responsibility to admonish the father for wrongdoing. Furthermore, while the son should be filial to his father, the father should be lovingly kind to him.

Nevertheless, though the moral obligation is mutual, there can be no denial that the Confucian ethics of filial piety has resulted in such practices as parental choice of spouses for their children, parental decision in all family matters, property-holding in the name of the father and ancestor worship (*q.v.*), practices that have been strongly opposed and largely rejected in modern times. Though these customs have changed, however, the basic belief that parents and children have special obligations to each other has remained.

Confucian ethical teachings in general and the doctrine of filial piety in particular have exercised tremendous influence over Korea, Japan and to some extent Annam. One important deviation is to be noted in the case of Japan, where the traditional respect for the sword has combined with some Confucian ethical ideas to form the code of Bushido (*q.v.*), or the Way of the Warrior. This would have been utterly impossible in China, where the superior man is not a man of the sword but of moral nobility; he is never a fighter but a scholar-gentleman.

**Social.**—Of all social institutions, the family is most important in Confucianism, partly because it is the natural ground for moral training and partly because it is the bridge between the individual and society. In Confucian China it has served as an economic, social and political unit, since members of the family have participated as a group in economic, social and political activities. It has been held together by common blood, property, prestige and responsibilities and, above all, common ideals. Wealth, honour, happiness, a large number of sons and longevity are family ideals, but the greatest of all is love of virtue. According to Confucian teachings there are five human relations in society: "Between father and son there should be affection, between ruler and minister, there should be righteousness, between husband and wife, there should be attention to their separate functions, between

elder and younger brothers, there should be order, and between friends, there should be good faith" (Mencius). Three of these relations are found within the family.

To help bring about the realization of these ideals of human relations, Confucianists have advocated two important social doctrines: rules of propriety and "rectification of names." By propriety is meant, in the narrowest sense, details of etiquette and ceremonies and, in the broadest, proper attitude and expression. Both a proper state of mind and correct conduct are necessary for a perfect social order. From the time of Confucius himself, Confucianists have taken propriety most seriously.

The doctrine of rectification of names, which also came from Confucius, means that the ruler should be a true ruler, the father a true father, etc.; in other words, no father should be so called unless he acts like one, and no ruler deserves his position unless he truly fulfills his function. Applied to society in general, the doctrine means that rank and status must be clearly distinguished and their corresponding responsibilities sharply defined; applied to logic, it means that names must correspond to actualities; applied to metaphysics, it means that reality and function must correspond to each other. Though the logical theory of rectification of names and the metaphysical theory of correspondence of reality and function are both important features, the doctrine of rectification of names is primarily ethical in character. At best it has led to insistence on sincerity, truthfulness and actuality in all things; at worst it has led to an undue regard for status. However, the emphasis on individual worth and the belief in the possibility of anyone's becoming a sage have prevented a rigid social stratification in China. Confucian moral and social teachings contributed in no small degree to the downfall of feudalism in the 3rd century B.C. and to the emergence of a "classless" society. Chinese nobility, aside from the emperor and his relatives, was based no longer on birth but on merit. Titles and ranks were determined not by heredity but by ability. The highest honour has gone to the scholar-gentleman.

All this does not disguise the fact that Confucianism championed a double standard for men and women. By "attention to their separate functions" is meant that the husband's responsibility is outside and that of the wife inside the home. In this sense they are equal; as the Confucian saying has it, "To be a *ch'i* [wife] is to be *ch'i* [equal]." But the husband is also the "standard" of the wife. A man could divorce his wife; could remarry and could have more than one wife, but similar rights were denied to women. In the name of moral integrity, Sung Neo-Confucianists imposed a specially rigid code of morals for women, who were required to protect their chastity under all circumstances and to swear complete loyalty to their husbands, living or dead. Modern reforms have done away with these inequities, but the central Confucian conviction that social relations should be morally determined has been maintained.

**Political.**—A similar moral concern is found in Confucian ideas about government deriving chiefly from Confucius and Mencius. The state is looked upon as an enlarged family headed by a sovereign who should be like a father, benevolent and devoted to the welfare of his people. There should not be two kings in the land any more than there should be two suns in the sky. As everything in the family belongs to the father, so all territory and all citizens belong to the sovereign. Such a system is obviously paternalistic and absolutistic. In the state, however, in contrast to the family, the people are considered to be more important than either the ruler or the territory. According to Confucian teachings, the sovereign should rule only by the mandate of Heaven. Whether or not the mandate is carried out is to be judged by whether or not "those who are near are happy and those far away desire to come." A ruler failing in the mandate should abdicate in favour of a virtuous man, or he should be overthrown, by revolution if necessary. This doctrine of revolution has never been abandoned by Confucianism. Founders of new Chinese dynasties usually have claimed that they had the mandate of Heaven to rule and have made some efforts, in the beginning of the dynasty at least, to prove it by promoting the welfare of the people. Japanese Confucianists, while they exaggerated the teaching of loyalty to the ruler to a point unac-

ceptable to Chinese Confucianists, never propagated the doctrine of revolution.

According to the Confucian standard, a ruler should rule by moral example and not by force. There must be laws, but only good men can make good laws, and governmental measures should be few and punishment light. In short, government should be in the hands of the educated and the virtuous. To implement this ideal, the system of civil service examinations was established. In the Han period officials were required to study the Confucian classics. Later, officials were recommended, and then promoted, on the basis of their knowledge of the classics. From A.D. 618 until 1905, they were selected largely through competitive examination on these classics, which was open to all without any discrimination because of colour, sex, age, social station or religious belief. The number of men who rose from humble circumstances to political prominence in this way was large, though inevitably the privileged minority had an advantage. After operating for nearly 1,300 years, the system finally became corrupt and decadent, ceased to meet the needs of the country and was abolished. Whatever its shortcomings, it provided social and political leadership for China, it kept alive the Confucian ideal of government; it subordinated military officers to civil officials; it offered an opportunity for ambitious and able persons to rise socially; and it gave China cultural homogeneity and continuity. Further, it reinforced the Enlightenment movement in 18th-century Europe, where it exercised appreciable influence.

**Educational.**—Through such devices as the civil service examination Confucianism had almost complete control of education in China for nearly 2,000 years. Until 1905 the educational system, texts and ideals were all Confucian. Fundamentally the Confucian objectives of education were to develop the individual human nature and to bring about a good society through investigation of things and cultivation of personal life, as taught in the *Great Learning*. The door was open to all; as Confucius said, "In education there should be no class distinction." Of course the number of persons who attended schools was necessarily small, for in an agricultural society literacy was not a necessity and most people were too poor to send their sons to school. But every community had a school—a result in large part of the Confucian idea that a major function of government and family was to educate the young—the immediate purpose of which was to impart knowledge and train character, the broader objective to provide leadership for the government by preparing students for the civil service examination. The central focus was a liberal education for the development of the whole man. In actual operation, however, study was confined to the classics, and this narrow scope and unchanging curriculum led to provincialism on the one hand and conservatism on the other. In time emphasis came to be placed almost exclusively on memorization and the writing of flowery compositions, thus discouraging intellectual curiosity and creative and critical thinking. By the 20th century it was clear that Confucian education was inadequate to meet modern needs, and the western type of education was adopted in its place.

The school, however, was only one part of the Confucian educational process. The home and the community were equally important. Many prominent Neo-Confucianists wrote moral codes for the home and "community compacts" for the clan to inculcate Confucian virtues. Very often imperial edicts, letters to children, community announcements and wills taught moral lessons. Some of these documents have been adopted as models and still have strong hold on society.

**Religious.**—Basically Confucianism regards religion as a form of education; in Chinese the word for both religion and education is *chiao*, "to educate." To the Confucianist religion exists for the purpose of moral cultivation. This does not mean that religion as understood by Confucianists is devoid of spiritual or supernatural aspects; Confucian humanism is not without a religious character. Confucius himself avoided discussion of spirits and life after death, and taught people to "respect spirits but keep them at a distance," not because he was irreligious but because he wanted men to direct their own destiny rather than allow the spirits to do so. He knew the mandate of Heaven; he prayed, be-

declared that Heaven was grand. Because of its religious tendency Confucianism has promoted ancient religious rites, including the worship of Heaven, the honouring of ancestors and the commemoration of great men, ever since it achieved supremacy. Traditionally the emperor, on behalf of the people, performed annual rites at the Altar of Heaven to give thanks and to pray for a good year. Ancestral rites have been regularly performed, and Confucian doctrine dictates that they be performed sincerely, not because ancestors will give rewards and punishment but in order to continue the human relationship, which should not be terminated with death. Temples were built for great men and seasonal rites performed for them, not in the belief that they had become gods but as expression of respect. Confucius was, of course, the greatest of the great, and a Confucian temple could be found in every prefecture. The great sacrifice was offered him, and the titles of duke and king were conferred on him from time to time. But with rare exceptions, he was never deified. Instead, the Chinese have called him "Great Perfection, Ultimate Sage and Foremost Teacher."

Confucianism has no sacred scripture, church, clergy or creed and is therefore not an institutional religion. It is religious, however, not only in its promotion of traditional rites but in its own philosophy. It does not condone belief in heavens and hells. Its theory of immortality is purely humanistic—that is, the immortality of virtue, wisdom and achievement. It believes in a naturalistic law of retribution according to which good and evil deeds will bring their own consequences. But to Confucianists the highest spiritual reality is Heaven. He is not anthropomorphic and "does not speak," as Confucius said; but he is superhuman, purposive, the source of truth and goodness, completely overwhelming and mysterious. Confucianists call their Way the "Way of Heaven" and Principle the "Principle of Heaven." In other words, Heaven is the ground of all principles and the source of the moral law.

**Historical.**—The moral law operates not only in society but in history also. As Confucianists see it, the passage of historical events demonstrates unmistakably that goodness leads to happiness, prosperity and peace, whereas evil invites suffering and chaos. As early as the Han, Confucianists began to interpret Confucius' *Spring and Autumn Annals*, a brief historical record of his own state, as embodiment of "subtle words and great principles," that is, hints and suggestions as to how moral principles are revealed in historical happenings. As to the meaning of history itself, Confucianists have held various theories. Some, following Mencius, believed that history consists of a series of order and chaos, one following the other. Others, taking their theme from the ancient *Book of Rites*, saw history as an unfolding in three stages, the Epoch of Chaos, the Epoch of Small Peace and the Epoch of Great Harmony; whereas families and nations remain distinct though in concord in the Epoch of Small Peace, they will all become one in the Epoch of Great Harmony, in which universal peace will prevail. Most Confucianists, however, have held the cyclical theory: the golden age lay in the past, the present age is one of decline, and a sage will appear to save the world and to usher in the golden age once more. Hence Confucianists have always looked to ancient sages as models, especially the legendary emperors Yao and Shun, represented by Confucius and all his followers as examples of perfect virtue and wisdom. Such backward-looking naturally intensified the conservatism of Confucianism.

It would be naïve, however, to conclude that Confucianists were merely backward-looking. When Confucius repeatedly offered Yao and Shun as standards, he was presenting concrete cases in history, which he might have manufactured himself, to show that his ideas were not "empty talks." He and his followers were seeking precedents, of course, but more than that, they were trying to demonstrate by actual past events the practicability of their doctrines and the way in which the moral law works. If they moaned the degeneracy of the age, it was to call attention to the urgent need for reform. The element of status quo in Confucianism has been strong, but there has been a good number of famous reformers.

The Confucian concept of history has produced two characteristics in the Chinese people. One is a strong sense of history, as evidenced by detailed records going back to ancient times and by

frequent reference to history in discussions on all subjects. The other is the belief in a future utopia on earth. The Chinese have strongly criticized the Buddhist and Taoist belief in a heavenly paradise as representing lack of faith in history.

**Scientific.**—The great respect for facts, plus the general spirit of humanism and naturalism in Confucian philosophy, should have helped it to develop natural science in China. Confucius admonished his pupils to acquaint themselves with the names of birds, beasts, plants and trees. The whole Confucian tradition is strongly imbued with the spirit of skepticism, which should be a stimulus to scientific inquiry. The ancient doctrine of investigation of things, which became an essential tenet of Neo-Confucianism, is essentially scientific in outlook and procedure. The Neo-Confucianists taught that even a blade of grass should be investigated, and that the investigation was to be both inductive and deductive. When Chu Hsi lectured on a hill and incidentally came upon some fossils, he studied them objectively and concluded that the top of the hill was once the bottom of a sea, thus discovering the nature of fossils several hundred years before it was done in Europe. But Confucianism never developed natural science, even after the Jesuit priests introduced western scientific knowledge into China in the 17th century. Among many possible explanations, the chief probably are that the Confucianists were primarily interested in social and moral problems, that they did not cherish the ideal of knowledge for its own sake and that as time went on they were increasingly involved in book study. They directed their objective inquiry to the study of texts, in which they did remarkably well but at the expense of mastery over nature. One of the outstanding ideas in Hsün-tzu was the control of nature. Had he instead of Mencius been dominant in Chinese history, Confucianists might have been attracted to science. But the supreme role was played by Mencius, whose chief concern was moral principles, and Chinese Confucianism has followed him.

**Artistic.**—Preoccupation with moral and social problems also characterized the Confucian approach to art. Early Han Confucianists seized upon the saying "In poetry, have no depraved thoughts" to moralize on ancient poetry and music and to insist that art must teach a moral lesson. They said that literature was to "embody the Way," that is, the moral law. Neo-Confucianists, most of whom were stern moralists, carried on the tradition and strengthened it. Hence Confucianism has been strong in historical writing, prose and poetry but weak in dance and music. When these were turned into social and religious rites their growth was checked. As to calligraphy and painting, particularly landscape painting, much of their inspiration came from Taoism, but since these are primarily literary arts, using the brush and ink, they have become arts of the literary man, who is inevitably a Confucianist. Needless to say, according to the Confucian standard the function of calligraphy and painting is not to entertain but to purify and harmonize the emotions. Since the drama and the novel often play upon vulgar emotions, they have been frowned upon by Confucianism.

### CONFUCIANISM IN MODERN CHINA

For 2,000 years Confucianism retained its hold on Chinese thought and culture. While it became more and more conservative, losing thereby its vitality, its spirit of rationalism, humanism and moralism never weakened. In the 19th century these characteristics became even stronger. The advent of empiricism, in reaction to earlier speculation, led to increased emphasis on action and practice, an inevitable development demanded by China's degenerate condition. It was also a natural revolt against excessive emphasis on textual criticism and flowery compositions, and the internal growth of Confucian thought gave it further impetus. In the 19th-century Modern Script school the Confucian classics were interpreted as an embodiment of "subtle words and great principles." This theory was advanced not to fortify Confucian speculation but, on the contrary, to criticize current conditions and to call for action, Confucius being characterized by the school as a man who tried to apply great principles to put society in order. The whole tenor of the school was for reform. At the same time, China's defeats in wars and the introduction of western technology

further convinced the Confucianists that China had to change. Yet they were still loyal to Confucianism. The obvious way out was a synthesis that came to be expressed in the famous slogan "Chinese studies for the fundamentals and western studies for practical use." The consensus of 19th-century Confucianists was that western knowledge could and should be used to build railroads and manufacture arms but that for moral and spiritual values Confucian teachings remained superior to those of the west. Thus there were two prevailing tendencies: the demand for action and the firm loyalty to Confucianism.

These two currents met in the person of K'ang Yu-wei, the latest outstanding Confucianist, who was the brain behind the radical but abortive reform of 1898. The philosophical basis for the reform was that Confucius was a reformer, that he conceived history to be progress in three stages toward the Epoch of Great Harmony, but that the world was then ready only for an Epoch of Small Peace. Attempts were made to reorganize the civil service examination system, establish modern schools, translate western works, encourage publication, promote labour and agriculture, build railroads, open mines, etc. In concept the reform was strictly Confucian, although in practical measures it was western.

The reform failed miserably, and a long series of Confucian setbacks followed. The civil service examinations were terminated in 1905. The monarchy, with which Confucianism had been identified over 2,000 years, was overthrown in 1911-12, and with it the Confucian religious rite of sacrificing to Heaven. The annual official sacrifice to Confucius in the temple in his native place was also discontinued in 1928. Although the empress dowager, in an attempt to salvage the crumbling Manchu empire, raised the traditional sacrifice of the middle order to Confucius in 1906 to the sacrifice of the first order, which had been reserved for Heaven, and made Confucius "counterpart of Heaven," there was no enthusiastic response. Likewise, the movement by K'ang and his followers to establish Confucianism as the state religion in 1913 found no support. At the same time, age-old Confucian institutions were in the process of disintegration. The arranged marriage system was gradually giving place to free choice. Equality of the sexes slowly supplanted the traditional double standard. The authority of the father was seriously weakened. Ancestral rites became less and less popular. Few temples, if any, were built for Confucius or great men in history. The Confucian classics were ignored. All these developments dealt a blow to the Confucian system that was almost fatal. The New Culture movement that began in 1916 virtually gave it the *coup de grâce*, for intellectuals, old and young, condemned Confucianism as incompatible with modern life, attacking particularly the fundamental Confucian doctrine of filial piety as exploitation of the son and its doctrine of feminine integrity as enslavement of women. The general cry was "Take down the sign board of Confucianism!"

While its institutions were toppling and its doctrines were being rejected, however, forces were already at work to give Confucianism new standing. In 1913 the draft constitution of the republic declared that "in the education of citizens the doctrines of Confucius shall be regarded as the basis of moral cultivation." Four or five years later, at a moment when many prominent intellectuals were demanding that the "old curiosity shop of Confucius" be destroyed, Sun Yat-sen, leader of the Nationalist revolution, was enunciating his theory that "it is easy to act but difficult to know." This theory is important not so much because of its own merits as because Sun dared to revive and preach a major Confucian doctrine, one that was part of the unbroken Confucian heritage. The ancient *Book of History* stated that "It is not difficult to know but difficult to act." Confucius and Mencius always insisted that words and action must correspond to one another, and Wang Yang-ming identified knowledge and action as one. Sun, a rebel, was now carrying on a tradition of an unpopular system. In 1923 he went a step further and declared that the time-honoured Confucian virtues of loyalty, filial piety, humanity, love, faithfulness, righteousness, harmony and peace were of the highest merit and necessary for a modern Chinese nation. In 1921 Liang Shu-ming, an intellectual and a leader of the New Culture movement, contended that Confucianism, in emphasizing the mean, had avoided the ex-

trêmes of Indian and western civilizations, and urged the Chinese to uphold and develop the Confucian *jen* as a dynamic, firm and strong force for a new life. His tremendously popular lectures did much to turn the tide away from contempt for Chinese civilization in general and for Confucianism in particular. A foremost leader of the New Culture movement, Hu Shih, also defended Confucianism as favourable to the scientific spirit and instrumental in reforms. In 1928 the traditional civil service examination system was modified and incorporated into the Nationalist governmental structure as one of its five main branches, and in 1934 the Nationalist government decreed that a national holiday be observed on Confucius' birthday, as Teachers' day. In the field of philosophy, in the 1930s Fung Yu-lan reconstructed rationalistic Neo-Confucianism with western logical concepts, while Hsiung Shih-t'ung transformed idealistic Neo-Confucianism by utilizing Buddhist terminology. (See CHINESE PHILOSOPHY.)

When the Communists gained control of China in 1949, Confucianism faced an uncertain future. The national holiday on Confucius' birthday was abolished. Old traditions, of which Confucianism formed a substantial part, were cast aside; the Communists do not look to past sages for sanction, they have not felt the need for a mandate from Heaven. The family system, the central Confucian institution, has been minimized. Nevertheless, the Confucian temple in his native place has been well kept, Confucian classics and commentaries have been published, and Communist leaders have said that they should learn from Confucius as they should learn from other great men and that they should absorb the "democrat elements" of Chinese civilization, which means largely Confucian civilization. Regardless of what the Communist government may do, Confucianism has shown its strength to weather all kinds of storms. It has survived both benevolent and ruthless regimes in China. In Japan it withstood the Meiji restoration, which raised Shintō to the supreme position and suppressed other systems, as well as the military decades of the 20th century, and has retained its influential status in Japanese family and society. In the meantime, the national holiday on Confucius' birthday continues to be observed in Formosa, where also the doctrine of filial piety is propagated with new vigour. In the west more and more study is devoted to Confucianism. Confucianism is changing, but it is reasonable to believe that it will remain essentially Confucian. See CONFUCIUS. For the development of Confucianism and Neo-Confucianism in Japan, see JAPANESE PHILOSOPHY. See also references under "Confucianism" in the Index.

Creel, *Confucius, the Man and the Myth* (1949, 1951); Wing-tsit Chan, *Religious Trends in Modern China* (1953); David S. Nivison and Arthur F. Wright (eds.), *Confucianism in Action* (1959).

**CONFUCIUS** (551-479 B.C.), China's most famous man, was a teacher, philosopher and political theorist whose ideas have deeply influenced the civilization of all of eastern Asia. The ultimate success of his doctrines was so great that it is difficult to believe that he was in fact a frustrated (though never embittered) man who never realized any of his dearest ambitions. The real story of his life and work has almost been lost in the wealth of legend that has grown up about his name. Careful investigation, however, has been able to separate the truth about the man from the posthumous glorification of the sage. Little is reliably known about his life. His ancestry is unknown, but he probably descended from impoverished nobility. His family name was K'ung. "Confucius" is a Latinized version of K'ung Fu-tzu, "Master K'ung." As a young man he was poor, and once made his living by keeping accounts. He was largely self-educated, but so diligent that he appears to have become the most learned man of his day. Learning was not, however, his greatest interest. He was deeply distressed by the misery that he saw on every hand. China was only nominally united; the king was a puppet, and even the various feudal states were in effect divided between powerful nobles who did as they pleased. The aristocrats made war as a pastime, and taxed their subjects, exhausted them with forced labour and oppressed them at will. In bad years starvation was common.

Confucius dedicated his life to the attempt to relieve the sufferings of the people. He believed that the solution must be fundamental: a reform of the government that would make its objective not the pleasure of the rulers but the happiness of their subjects. To this end he advocated such measures as reduction of taxation, mitigation of severe punishments, and avoidance of needless war (which was often pleasant and profitable for the aristocrats). The rulers of his native state, Lu, paid little attention to his admonitions. His lifelong objective was to occupy a commanding administrative post in which he could put his ideas into practice. It is not surprising that he never obtained one; from the point of view of the rulers his ideas must have seemed dangerous.

CONFUCIUS, 17TH-CENTURY SCREEN PAINTING BY THE JAPANESE MASTER KANŌ TANYŪ

While waiting for his opportunity, which never came, he talked to younger men about his principles. Gradually a group of them formed about him, as disciples who recognized him as their teacher. Since Confucius was unable to apply his principles, he laid increasing emphasis on teaching them to younger men for whom, when he considered them sufficiently educated, he sought posts in the government. He was remarkably successful in placing his students in positions of real authority, in which some of them proved extremely capable. But those who were most successful were more compromising than their teacher, and his doctrines had little practical effect in his own day. Eventually Confucius was given a post with an impressive title, probably for the sake of appearances, but when he realized that he had no actual authority he resigned in disgust. Although then in his fifties, he set off on what proved to be a decade or more of arduous and sometimes dangerous travels through various states, seeking a ruler who would confide to him the administration of his state. Finally, at 67, he responded to the invitation of some of his disciples to return to Lu. There he continued his teaching until his death at 72.

**Teacher and Scholar.**—Before Confucius, aristocrats had had tutors and government officials had instructed their subordinates in the necessary techniques. But Confucius seems to have been the first private teacher in China, and the first to use his teaching as an instrument of reform. His methods were quite informal. There is no record that he lectured; rather he conversed with his students in small groups or individually. He studied the character of each disciple, and sought to develop the total man. His prime insistence was upon sincerity, and his whole teaching was based upon ethics. He regarded statecraft as the application of ethics in a broader field. To furnish and deepen his students' minds, he had them study history, poetry and music. To equip them to act effectively in the world he schooled them in the theory and practice of human relations, and taught them how to conduct themselves in a wide variety of situations. His teaching was not dogmatic or authoritarian; he was not affronted if his students disagreed with him, and sometimes acknowledged that they were right. Typically he merely asked questions, and insisted that they find the answers for themselves. He said, "If, when I point out one corner of the subject, the student cannot work out the other three for himself, I do not go on." While Confucius did not advocate revolution, his educational activities were profoundly revolutionary in two senses.

By emphasizing the right and duty of every individual to make basic decisions for himself, he undermined the foundation of authoritarian government. By accepting as students even the poorest and humblest individuals, if they were intelligent and earnest, he destroyed the monopoly which the aristocracy had enjoyed in its control of the techniques of government.

The activities of Confucius as a scholar have been greatly exaggerated.

He was learned and he used books in his teaching, but his interest in books as such was distinctly subordinate to his passion for reform. Although a great number of books have been ascribed by tradition to his authorship, it is improbable that he composed any of the books that have come down to us, and it is not even certain that he edited any of them.

**His Religion and Philosophy.**—Although Confucianism has sometimes been called a religion, Confucius was not a religious leader in the usual sense. He was undoubtedly a religious man, in that he felt that there was somewhere in the universe a force on the side of right. He also took a good deal of aesthetic pleasure in religious ritual. But he considered a large part of the religion of his day to be sheer superstition, and condemned many of its practices. His philosophy was not founded upon supernaturalism in the slightest degree. Chinese philosophy has given relatively little attention to metaphysics, epistemology and logic. In this it reflects the tendencies of Confucius, who may fairly be called its founder. It does not follow that he was a disorderly thinker because he did not stress logic. Rather, he was doubtful that one could learn about the real world merely by manipulating words together. His theory of knowledge had some resemblance to that which underlies modern science, in that it was nondogmatic and empirical. He said, "No doubt there are those who find it possible to act without first understanding the situation, but I am not one of them. To hear much, select what is good, and follow it; to see much and take careful note of it; these are the steps by which one ascends to understanding."

Humanity was central in his philosophy. "Virtue," he said, "is to love men. And wisdom is to understand men." The concept of the family has always been the pivot of Chinese culture, and Confucius regarded mankind as one large family. It was one of his disciples who said that "within the four seas all men are brothers." Sincerity and reciprocity, then, should be one's guiding principles. "The truly virtuous man," Confucius said, "desiring to be established himself, seeks to establish others; desiring success for himself, he strives to help others succeed. To find in the wishes of one's own heart the principle for his conduct toward others is the method of true virtue." In accord with these ideas he believed that the state should be a wholly co-operative enterprise. This belief was completely at variance with the theory then in vogue. Aristocrats were believed to be descended from divine ancestors, and to rule by virtue of the authority and the powerful assistance of their ancestors. Confucius completely ignored this idea; eventually it disappeared in China, and Confucius was certainly in part responsible for its going. The right to govern, Confucius held, depended upon the ability to make the governed happy. And this in turn depended upon the possession of virtue and ability. Thus anyone possessed of virtue and ability might properly govern, and no one without them had the right to power. Confucius interpreted this in practical terms as meaning that the hereditary rulers should confide all administrative power to ministers who should be selected for their ability and virtue.

These qualities Confucius did not intend to leave to chance. He believed that, while individuals undoubtedly vary in their inherent virtue and abilities, these may be greatly developed by means of proper education. Therefore he laid very great stress on education designed to develop abilities and to strengthen character. While he did not advocate advanced education for all, he did believe that some education must be given even to the humblest citizens, for two reasons. First, since ability does not depend on birth, only a wide dissemination of education can ensure that all of the most capable will be given the opportunity to develop themselves, for their own good and that of society. Second, since the state is a co-operative enterprise an enlightened citizenry is necessary to permit it to operate effectively. Thus, while he considered war an evil, he believed that when it must be prosecuted this should be done vigorously, and he believed that the prime necessity for success in war was an army entirely clear as to why it was fighting and thoroughly convinced of the justice of its cause.

**His Influence.**—The difference between the ideas of Confucius and some aspects of what has later been called Confucianism is so great that one may be tempted to question the extent of his in-

fluence. It is the common fate of great men to have their ideas distorted by posterity. Yet if we look at the form of Chinese government, as it existed from the Han dynasty (202 B.C.—A.D. 221) onward, the large outline is strikingly reminiscent of the ideal of Confucius. In theory and very largely in practice the administration was controlled by ministers; and these ministers were selected, for the most part, not for their ancestry but for their personal qualities, so that a man of very humble origin could and sometimes did rise to wield the paramount power over the entire Chinese empire. In many other ways, also, the ideas of the obscure teacher of Lu have exercised such a formative influence upon the culture of China, and of much of the far east, that Confucius must be counted one of the most influential men in world history.

**CONGÉ D'ÉLIRE** (Norman-French for "permission to elect") signifies the English sovereign's permission for the dean and chapter of the cathedral of a vacant bishopric to proceed in regular chapter to a new election. Before the Norman Conquest it was the king's prerogative to appoint bishops to vacant sees. This later came to be contested by the popes, though the sovereign was usually successful in securing the appointment of his nominees. The appointment of bishops was vested in the crown by the Annates' Statute (1534) of Henry VIII (see ANNATES). The statute provided that when the king's *congé d'élire* was sent to the dean and chapter a "letter missive" accompanied it in which was given the name of the person to be elected. In the event of a delay of 12 days to elect, the king might appoint to the see by letters patent; if, however, the dean and the chapter delayed more than 20 days to elect in accordance with the "letter missive," they became liable to the penalties of *praemunire*. Another act was passed (1547) providing for nomination by letters patent in all cases, but this was repealed under Mary Tudor. The 1534 act, reinstated by the act of supremacy (1559), has operated in the Church of England ever since. (J. W. L.)

**CONGLETON**, a municipal borough of Cheshire, Eng., 31 mi. E. of Chester by road. Pop. (1961) 16,823. It is in a deep valley on the banks of the Dane. Mentioned as Congelton in Domesday Book, the borough was incorporated by a charter of Henry de Lacy in 1272, and later the right to hold fairs and a weekly market was granted by Edward I. A general market is held weekly on Saturdays and a cattle market on Tuesdays. In the town centre modern shops blend comfortably with traditional black and white timbered buildings. There is a public park and an open-air swimming pool.

In 1751 the silk industry was introduced to Congleton and prospered until its decline in 1824. After a period of acute unemployment, the fustian and velvet cutting industry was introduced in 1867. Textiles remain the principal industry and include the manufacture of hosiery, knitwear, cotton garments, tablecloths, bedspreads and ribbon. Other industries include the production of mineral waters (soft drinks), cardboard, cattle foods, electrical equipment and television antennas.

**CONGLOMERATE**, in petrology, is the term used for a coarsely fragmental rock consisting of rounded pebbles or boulders set in a finer-grained matrix. The name is from the Latin *conglomerare*, "to form into a ball." If the pebbles are angular, the rock is termed *breccia* (q.v.). Conglomerate is thus merely consolidated gravel or boulder beds. The coarser constituents have become rounded by weathering and by attrition during transport by streams and the waves of the sea. Their size varies considerably; they may be 10 or 20 ft. in diameter, but are commonly a foot or less. Quartzites, cherts and flints and vein quartz, being among the hardest and most durable of all rocks, are especially abundant in conglomerates, but granite, gneiss, sandstone and limestone also occur. Conglomerates are less likely to be formed where chemical weathering predominates, as in many tropical areas, and in comparison to finer-grained sediments they occur in more restricted areas or belts. The matrix in which the

building, as in the earlier strata of Pennsylvanian or Upper Carboniferous Age (Pottsville Conglomerate, Millstone Grit, etc.), or in the Triassic of northwestern Europe, North America and New Zealand. For crush conglomerate, see BRECCIA; see also SEDIMENTARY ROCKS. (C. K. W.)

**CONGO (REPUBLIC)** (RÉPUBLIQUE DU CONGO), a state of equatorial Africa, a member of the French Community (former Territory of the Middle Congo or Moyen-Congo, French Equatorial Africa). Area 134,749 sq. mi. Pop. (1962 est.) 864,679. The Republic of Congo is bounded on the north by Cameroon and the Central African Republic, on the east and the south by the Democratic Republic of the Congo (formerly Belgian Congo) and the Angolan exclave of Cabinda, and on the west by the Atlantic ocean and Gabon.

**Physical Geography.**—The country belongs to the Congolese basin, of which it makes up only a small part. In the east on the right bank of the Ubangi and the Congo, lies a plain, formed from the Quaternary alluvium of the centre of the basin and crossed by a series of black-water rivers and swamps. The branches of these rivers often intermingle and they multiply and divide before flowing into the Ubangi or the Congo. Among them are the Motaba which enters the Ubangi at Dongou, the Likouala, the Sangha (Sanga) and the Alima, all of which are often navigable. The Congo-Ubangi is navigable for over 1,500 mi. above Brazzaville. The alluvial plain rises in the west and gives way to a plateau of reddish Secondary sandstone and white Tertiary sandstone. The valleys are sunk into it, as is the Congo upstream from Stanley pool. In the west these sandstones rest on the rocks of the Archean core, which are extremely varied and give greater complexity to the relief. On the granites of the Monts du Chaillu rest the sandstones and schists of the Franceville basin and of Mayombé (Mayumbe), or schists, limestones and conglomerates. Between hills of hard rocks, the valleys widen on the schists formation, in particular the valley of the Niari, which is the principal way of penetration. It is closed on the west by the massif of Mayombé (2,411 ft.), which is formed from granites and quartzites, where the Niari is enclosed in wild gorges. On the south it is dominated by the sandstone escarpment of the "Plateau of the Cataracts" which surrounds the Congo downstream from Stanley pool. The Mayombé massif borders a coastal plain, formed chiefly of clayey Pliocene sandstones and closed by a coastal belt which isolates lagoons.

As the equator runs through the republic, the climate is the whole equatorial, though the thermal equator is farther to the north. The rain forest extends only across the plains except to the north of the equator. Savanna appears on the Central African Republic frontier where there is a dry season, in the country of Bateke because of the sandstone, in the valley of the Niari sheltered by Mayombé and in the coastal plain which is freshened by the Benguela current. (J. D. W.)

**History.**—Prehistoric sites have been discovered at Brazzaville and in the Niari valley. Three levels have been distinguished: Lower Paleolithic (coarse bifacial tools), Sangoan (bifacial tools and flakes) and Lupemban (pointed and tranchet tools).

The Pygmies, the early inhabitants, appear to have come from the Ubangi. Of the Kongo, who seem to have arrived from the Kwango (Cuango) about the 15th century, the Vili group occupied the coast while the Sundi group crossed the river farther east. These groups founded the two kingdoms of Loango and Kakongo.

which were nominal vassals of the great kingdom of the Congo. The Stanley pool region was occupied by the Teke (the kingdom of Anzico) whose king, the makoko, was elected by the chiefs and wore a great collar of flat copper and a panther skin. To the northeast were the Mbocchi, who lived in fortified villages, and then the marshes of the Likouala and Sangha, occupied by the "water people" and Pygmies. (*See AFRICA: Ethnography [Anthropology]: West Central Africa.*)

In 1482 the Portuguese Diogo Cam discovered the mouth of the Congo. In the 18th century the coastal kingdoms received a superficial Christianity which disappeared with the departure of the missions. The slave trade was carried on through the ports of Cabinda, Loango and Mayoumba (Mayumba). The *pomberos*, former Portuguese slaves, traveled as far as the pool and returned with cargoes of slaves procured by the Teke, while the coastal chiefs levied dues in the form of guns and loincloths. The suppression of the slave trade in the 19th century hastened the collapse of the kingdoms.

In 1877 H. M. Stanley (*q.v.*), traveling down the Congo, discovered Stanley pool and then with difficulty reached the coast through the river's rapids. Pierre Savorgnan de Brazza (*q.v.*), who ascended the Ogooué, was in 1878 repulsed by the Furu on the Alima, but in 1880 he reached the pool and made a treaty with the makoko by which the latter ceded his rights to France. A post established at Ntamo (Brazzaville) was entrusted to the Senegalese sergeant Malamine who prevented Stanley from taking possession. Brazza reconnoitred the Niari-Kouilou route to the coast, which avoided the rapids, and occupied Loango and Pointe-Noire (*q.v.*).

Treaties made in 1885 and 1887 fixed the frontiers with Portuguese territory and the Congo Free State. In 1891 the colony of French Congo was created. Various missions made their way up the Sangha and a treaty in 1894 fixed the Cameroun frontier northward of Ouessou. In 1898 Brazza, who had been appointed commissioner general, was recalled to France and large concessions were granted. Brazza in 1905 accepted a mission to investigate charges of exploitation of the natives in the colony, and the concessions were restricted. The Franco-German agreements of 1911, which ceded to Germany the Sangha valley as far as the Congo, were annulled by World War I. Brazzaville became in 1910 the capital of French Equatorial Africa.

In 1940 the Congo rallied to Free France. Gen. Charles de Gaulle and the governor general, Félix Eboué, in Feb. 1944 held the conference at Brazzaville which heralded France's new colonial orientation. In 1946 Congo became an overseas territory of France, with representatives in the French parliament and an elected territorial assembly. The "cadre law" of 1957 gave it an elected government. In Nov. 1958 Congo became a republic of the French Community (*q.v.*). The priest Fulbert Youlou was elected president, and after some sanguinary incidents between Kongo and Mbocchi, a coalition was formed. The agreements transferring to the republic the powers formerly held by the Community were signed in Paris on July 12, 1960, and on Aug. 15, 1960, independence was proclaimed. (Hu. Dk.)

**People.**—Of the total population in 1962, about 10,000 were nonnatives. The density was 6.4 per square mile. Some peoples seemed to be decreasing in number; e.g., the Likouala, whose birth rate was 25 per 1,000, while the mortality rate was 30 per 1,000. The principal tribes are Congolese in the northeast like the Bangi, pushed back by the Teke who occupy the centre of the country. In the south, between Brazzaville and the coast, live related tribes, the chief of which are the Kongo and the Vili. All speak languages of the Bantu group. Besides Brazzaville (*q.v.*) and Pointe-Noire, towns of importance are Impfondo, Fort-Rousset, Dolisie and Libreville.

**The Economy.**—The forest has been partially cleared and has been damaged almost everywhere. Cassava is grown as the main subsistence crop. Two regions, however, the valley of the Sangha and that of the Niari, are suitable for the cultivation of products for export. In particular in the valley of the Niari, which is close to the Congo-Ocean railway, there are plantations devoted to cassava, and also peanuts, fibre plants and sugar cane and to stock raising, all of which developed after World War II.

An agricultural post was set up to improve the maize and sugar cane crops, together with research institutes for oil and oleaginous products and for fibre plants. On the slopes of the Monts du Chaillu plantations of Hevea and oil palms were being developed during the 1960s. In Mayombé there are deposits of gold and diamonds and at Mfouati and Mindouli, near the railway, lead ores have been discovered, in addition to the known copper area. Processing industries have been developed at Brazzaville and Pointe-Noire. In the 1960s a dam was planned on the Kouilou (the lower reaches of the Niari), 55 mi. across country from Pointe-Noire, which would provide 7,000,000 kw.hr. for industry, including the aluminum industry at Pointe-Noire.

**Communications.**—The Republic of Congo has no natural outlet to the sea, so that transporting exports and imports presents great difficulties. The Congo, while navigable above Brazzaville, is not so downstream where it is, moreover, in former Belgian territory. The solution has been provided by the Congo-Océan railway, from Brazzaville to Pointe-Noire, which makes use of a deepwater port. The railway was begun in 1921 and finished in 1934 in spite of great difficulties; it is 321½ mi. long and equipped with diesel locomotives. This railway is supplemented by a river system, which is good on the Congo and the Ubangi and poorer on the Sangha, and by a road network, uneven in quality, of 4,878 mi. Air transport is used for valuable cargo, the main airport being at Maya-Maya 2½ mi. from Brazzaville. Exported products are principally wood, oils, lead, gold and cocoa and imports are food products and tools. (J. D.)

**CONGO, DEMOCRATIC REPUBLIC OF THE** (République Démocratique du Congo; formerly the Belgian Congo, an independent country of Equatorial Africa, occupies the major part of the basin of the Congo River and a small part of the basin of the Upper Nile. Area 905,063 sq.mi. (2,344,116 sq.km.). Bounded on the west and southwest by Angola, it has a coastline of only 25 mi. (40 km.), extending north from the mouth of the Congo to the Angolan exclave of Cabinda; the southern bank of the Congo River mouth is in Angola. The republic is bounded northwest and north by the Congo Republic and the Central African Republic (formerly parts of French Equatorial Africa); northeast by Sudan; east by Uganda and Tanzania; and southeast by Zambia. Burundi and Rwanda lie northeast of Lake Tanganyika. The capital is at Kinshasa (*q.v.*; formerly Léopoldville).

### I. PHYSICAL GEOGRAPHY

The country generally comprises a plateau about 1,000 to 3,000 ft. (300 to 900 m.) above sea level covered in the north centre with dense tropical rain forest and in the south mainly by park savanna with some forests in the valleys.

**1. Geology.**—The geology of the Congo is as yet incompletely known; the rocks are often very decomposed superficially and fossils are generally few or nonexistent. Two main unities can be recognized, the underlying and the covering formations. In addition, between Boma and the coast is a narrow littoral band of Secondary and Tertiary marine formations, with occasional bituminous seepage. The lower formations are often metamorphic and are of Precambrian Age, the oldest being more than 3,320,-

000,000 years old. They sometimes enclose granite masses, and basement rock outcrops are seen. In Sud-Katanga folded Precambrian limestone and sandstone formations contain ores of copper, cobalt, uranium, lead, cadmium, and zinc. In Nord-Katanga and in Sud-Kivu the older formations contain cassiterite. Gold is found chiefly in Kibali-Ituri, Nord-Kivu, and Sud-Kivu.

Covering layers occupy vast surfaces. They include sands, clays, and sandstones and are almost always of continental origin, though there are traces of a marine invasion in the Cretaceous Period on the edges of Kasai-Occidental and Kasai-Oriental and in the Jurassic in the region of Kisangani (formerly Stanleyville). They were deposited from the end of the Primary Era (strata of the Lukuga series in Katanga enclose a little coal of low quality); their formations are chiefly Secondary (the Lualaba and Kwango series) and Tertiary (polymorphous sandstones and ochre sands belonging to the Kalahari System). More recent formations (late Tertiary and Quaternary) cover the centre of the Basin, often showing lateritic agglomerations near the surface.

The Congo Basin began to be formed in the Cretaceous Period. During the Tertiary, risings and sinkings formed the mountains and depressions of the eastern region. The volcanic manifestations of the region of Lake Kivu began at the close of the Tertiary and have continued until modern times.

**2. Physical Features.**—The Congo River (*q.v.*) flows through a vast basinlike plateau not exceeding 1,015 ft. (309 m.) above sea level at its central part, around Lakes Tumba and Léopold II. Two-thirds of its drainage area is within the republic. On the right bank of the river, below Matadi, stretches the hilly region of Mayumbe. Southern Congo contains the plateau of Kwango (2,300 ft.) near the Angola border, and the Kasai and Katanga plateaus. The latter include the lesser plateaus of Lubumbashi (formerly Elisabethville) (3,600 ft.), Manika (4,800 ft.), Kundelungu (5,100 ft.), and Kibara (5,600 ft.) and enclose such depressions and plains as Kamalondo-Upemba, the Lufira Plain, Lake Mweru (Lac Moero), and the Luapula Valley. In the north low plateaus divide the Congo Basin from those of the Chad and the Nile. In the east, the edge of the basin has been steeply raised. A veritable mountain chain runs along the edge of the depressions which form part of the western Great Rift Valley. In these depressions are, from south to north, Lakes Tanganyika, Kivu, Edward, and Albert (*qq.v.*). To the north of Lake Kivu the volcanic cones of the Virunga rise above great fields of lava. Between Edward and Albert lakes the Ruwenzori Range (*q.v.*; the Mountains of the Moon), on the border with Uganda, forms the highest point of the region, its summit covered by perennial snow. The central basin is a region of low plateaus and terraces, with little cliffs overhanging the sometimes marshy valleys.

**3. Climate.**—On and about the Equator the temperature varies little from day to day. The mean annual figure at Eala, practically on the Equator, is 77° F (25° C), the hottest month being February. Greatest rainfall occurs in April–May and October–November, and the annual precipitation at Eala averages 71 in. (1,800 mm.). Southward the temperature increases in range and average, the double maximum of rainfall is strongly marked and January and February tend to be less wet. There is a dry season (June, July, August). In the coast region, washed by the cool Benguela Current, and in the southeast highlands there is a dry season from June to October; July and August are the coolest months. Farther south on the Katanga Plateau the temperature range is wider and the mean annual temperature lower. Total rainfall may be 55 in. (1,400 mm.); little rain falls between May and September, but there is no double maximum.

**4. Vegetation.**—Rain forest occupies the north-central part of the basin between latitude 4° N and 4° S and extends to the western and eastern boundaries. Describing the forests of the Maniema country (now in Sud-Kivu Province), David Livingstone wrote:

Into these primeval forests the sun, though vertical, cannot penetrate, excepting by sending down at mid-day a thin pencil of rays into the gloom. The rain water stands for months in stagnant pools made by the feet of elephants. The climbing plants, from the size of a whipcord to that of a man-of-war hawser, are so numerous, that the ancient path is the only passage. When one of the giant trees

falls across the road it forms a wall breast high to be climbed over and the mass of tangled ropes brought down makes cutting a path round it a work of time which travellers never undertake.

Extensive forests also occur, to the north and south of the main forest, that are almost entirely composed of arborescent Leguminosae called *limbali*, about 100 ft. (30 m.) high, and in the basin of the upper Ituri-Aruwimi are vast areas of Uganda ironwood. By the river banks occur the "gallery" formations.

In the equatorial forests an abundant variety of trees includes some deciduous ones among the evergreen. Up to 180 ft. or more in height, they are hung with lianas, while epiphytic mosses and lichens cling especially to the topmost leaves and branches where there is light. In the darkness below there is little undergrowth. The great mixture of trees includes the African oak, mahogany, red cedar, and walnut, the silk-cotton tree, and other economically valuable kinds. Among the climbing vines are *Landolphas*, which produce rubber. Where the original forest has been cleared, for food or timber, secondary forests arise. Typical of these are the oil palms with other small trees and undergrowth. In the lower courses of most rivers and other parts flooded during heavy rainfall, the forests consist of silk-cotton, copal (*Copaifera*), and evergreen leguminous trees; in the swamps and permanently flooded areas, they are largely composed of euphorbias.

Another type of forest is found in the extreme south of Bandundu Province and in Katanga: this is forest with little undergrowth, where the trees are smaller and more spaced and lose their leaves in the dry season; most of the trees belong to the legume family and include acacias, *Brachystegia*, *Isobertina*, and *Berlinia*. Other trees include *Uapaca*, *Monotes*, and *Sterculia*. On the higher lands of the east, and especially on the slopes of the Ruwenzori, there are ranged in tiers shade-loving mountain forest, dry forest, grasslands, subalpine formations, and alpine grassland. These mountains are well known for their tree heathers, tree lobelias, and giant groundsel. The low banks of the Congo estuary bear red mangroves.

The equatorial forest is surrounded by a ring of savannas and steppes. The edge of the forest is much indented; toward the south it spreads into the valleys. Bandundu, Kasai, Katanga, and the northern regions are covered by vast savannas. The commonest grasses are tall, like elephant grass. These savannas are dotted with low trees and stunted shrubs with knotted trunks, such as *Hymenocardia acida*, which is widespread.

**5. Animal Life.**—A distinction may be made between the animals of the forests and those of the open savannas and grasslands. Others inhabit both the dry forests of Katanga and the eastern mountains. The forests are particularly the home of anthropoid apes and of many kinds of monkeys; chimpanzees are found in the equatorial forests, gorillas in the mountains of the east, and baboons in the more open country. Among rare animals peculiar to the forest or scrub regions are the okapi, giant wild boar, pygmy elephant in the swamps, and white rhinoceros and giraffe in the northeast. Lions are found in Katanga and in the grasslands and scrub surrounding the great forest, leopards everywhere, and cheetah, zebra, wild dogs, and the black rhinoceros in Katanga. Elephants, wildcats, tiger cats, buffaloes, antelopes, and wild hogs are found in both wooded and open country. Hyenas, jackals, and civets are abundant, especially in the east. Smaller animals include porcupines, squirrels, rats, hares and rabbits, pangolins, and bats. Hippopotamuses and crocodiles are common in the rivers and huge manatees in the Lower Congo. Whales and dolphins are found off the coast.

The Congo's parks include the Upemba (4,600 sq.mi.), in Sud-Katanga, a refuge for elephant, zebra, buffalo, and antelope (including eland and bubalis); Albert (3,160 sq.mi.), in Nord-Kivu adjoining Lake Edward, which includes the Virunga (Virunga) volcanoes, the Ruwenzori, and the Semliki Plain and where may be found mountain gorilla, buffalo, elephant, black rhinoceros, and giraffe; and, on the Sudan frontier, Garamba (1,950 sq.mi.) with elephant, hippopotamus, white rhinoceros, and giraffe. See also NATIONAL PARKS AND NATURE RESERVES.)

Bird life is abundant, though few of the birds are peculiar to the Congo. Pelicans frequent the larger rivers; cormorants

cranes, storks, herons, geese, ducks, vultures, eagles, owls, and bustards are more or less common, as are also the weaverbird and the whydah bird, cuckoos, pigeons, swifts, and the oxpecker. The spur-winged plover is the companion of the crocodile. There are more than 20 species of sunbirds and three or four species of parrots, the gray parrots being extremely common. Reptiles include pythons, the tree cobra, puff adder, and other vipers among snakes; tortoises, lizards, and chameleons. Lakes and rivers are well stocked with fish: catfish, electric eels, tiger fish, and others.

Insects, including bees and wasps, beetles, butterflies and dragonflies of gorgeous colouring, are innumerable, as are centipedes (up to eight inches long), scorpions, and spiders. Termites and ants, including the driver ant, are common, and the "ant hills" of the termites are a characteristic feature of many parts of the country. Ticks and mosquitoes are plentiful and include the disseminator of malaria; tsetse flies that carry sleeping sickness are also widely distributed. (HE. NI.)

## II. THE PEOPLE

The people of the Democratic Republic of the Congo are subdivided into a great variety of well over 200 tribes, many of which may be grouped together into larger culture clusters. Most of the tribes speak various Bantu languages (*q.v.*), but in the northern Congo there are also Sudanic and Nilotic speakers (*see* AFRICAN LANGUAGES). Moreover, up to 300,000 Pygmies, living in close contact with Bantu or Sudanese, whose languages they have adopted, are dispersed throughout the Central Congo rain forest. The Congo tribes have widely different origins, and many of them are culturally and historically linked to different groupings established in the neighbouring territories. The larger tribes include the Kongo, Luba, Lunda, Mongo, Nandi, Zande (Azande), Babwa, Lega, Kuba, Kumu-Bira, Ngbandi, Bwaka, Pende, and Tetela. All tribes are subdivided into many territorial and kinship groups and exhibit widely different cultural features.

Except for the greater part of the Pygmies, all Congolese peoples now practise shifting hoe cultivation, and more intensive agricultural systems have been introduced. Food gathering and hunting, however, are still very important among the Pygmies and many peoples in the central part of the republic, for whom hunting remains socially and ritually prominent. Fishing, too, is done on a considerable scale on the Congo River and its main tributaries, the great lakes, and the swamps. Most economic activities are shared by men and women according to a rigid pattern of labour division. Some eastern Congolese are sedentary pastoralists. Ownership and usage of land are generally controlled by local lineage groups, but eminent domain on land may reside with divine kings. Generally, individuals have secure title to land usage. Pottery, basketry, weaving, carving, and ironwork are highly developed. Gourds are widely used as vessels and bark cloth and skins as clothing. Fine carved masks, statues, seats, headrests, ceremonial axes, doors, etc., in wood, ivory, and bone, are known from many southern tribes.

Descent systems are generally patrilineal or matrilineal, but double-descent systems and non-unilineal descent groups are found, and relationships based on affinity, complementary filiation, friendship, and various alliances are also common. Marriages are usually established by marriage payments, small or large, but exchange marriages, elopement marriages, and replacement of wives occur. Polygyny is common, and widow's inheritance (brother's wife; father's wife; mother's brother's wife) is much practised. Preferential marriages—*e.g.*, between cross-cousins—and different forms of ritual marriages are permitted by some tribes. Formal age sets exist in only a few areas; closed associations, corporations, and cult groups are often found. Political structures range from elementary band organization and small autonomous kinship groups to elaborate segmentary structures, and from petty chiefdoms to large feudal or military states and federative monarchies.

Most Congo tribes practise ancestral cults and worship different kinds of spirits; there is also a general belief in a supreme being. In most societies special status is ascribed to twins, diviners, medicine men, rainmakers, and different kinds of specialized priests

and shamans. Oral literature (myths, proverbs, legends, songs, tales, and epic cycles) is extremely rich, as are dancing and some other dramatic representations. Though about 4,000,000 Congolese live under urban and semiurban conditions, many of them have preserved close links with their tribal region. (*See also* AFRICA: *Ethnography* [*Anthropology*]: *West Central Africa*.)

Before independence the Congo had about 580 Roman Catholic missions with more than 3,000 European and 780 African priests; there were also about 2,600 European and 750 African nuns. The number of African Roman Catholics was estimated at 4,220,440. Protestant missionaries belonging to many denominations exceeded 2,500 (about 1,500 European and 1,000 African). The number of Protestants was estimated at more than 800,000. There were also about 100,000 Muslims. The Congo is French-speaking. The most important African languages are, in the west, Lingala and, in the east, Swahili. (D. P. B1.)

## III. HISTORY

The history of the region prior to its becoming an independent republic in 1960 is to be found in the articles BELGIAN CONGO and AFRICA: *History: Central Africa*.

The resolutions of a Belgian-Congolese round-table conference on independence (January–February 1960) in Brussels were approved by the Belgian Parliament. From April 26 to May 16 an economic conference met there to agree on economic, financial, and social cooperation. The provisional constitution was signed on May 19, 1960, by King Baudouin. In the subsequent elections the left-wing Congolese National Movement (Mouvement National Congolais; MNC), led by Patrice Lumumba, emerged as the strongest party in both central and provincial assemblies and had the support of 74 out of the 137 seats in the House of Representatives. The first national government was formed on June 24, with Lumumba as prime minister. His political rival, Joseph Kasavubu, leader of the Alliance des Bakongo (Abako), was elected head of state. On June 30 King Baudouin proclaimed the new state's independence in Léopoldville.

Confusion developed almost at once in many areas, and the situation rapidly became more serious with the mutiny of the Congolese Army. Moïse Tshombe, provincial president in Katanga, declared Katanga independent on July 11, and Belgian forces arrived there to protect Belgian mining interests. On July 14 the United Nations Security Council acceded to Lumumba's request to send a UN force to the Congo. Although there was a ready response to the request of the secretary-general, Dag Hammarskjöld, for military help, the UN force was handicapped by his insistence that, in accordance with the Charter of the UN, it must not become a party to internal conflict or influence the constitutional issues. Lumumba, therefore, could expect no help against the secessionist Katanga Province or any other rebels. When he then sought and received aid from the Soviet Union, Kasavubu on Sept. 5 dismissed him and appointed Joseph Ileo prime minister in his place. Lumumba might still have rallied widespread support if Radio Léopoldville had not been closed down by UN forces, for on Sept. 13 Parliament voted him full powers. On Sept. 14 the army leader, Col. Joseph Mobutu, with UN approval, seized power and dismissed the president and both prime ministers, though he later came to a working agreement with Kasavubu. The central legislature no longer operated effectively. On Dec. 1 Lumumba was arrested by Mobutu's forces. He was later transferred to Katanga, and it was announced on Feb. 13, 1961, that he had been killed after escaping.

The end of 1960 saw the Congo divided into various rival regions. Kasavubu and Mobutu held an uncertain authority in the provinces of Léopoldville and Équateur; Antoine Gizenga, who had been deputy prime minister to Lumumba and had proclaimed himself Lumumba's successor, exercised from Stanleyville some influence over Orientale and Kivu provinces; Tshombe claimed to be head of the independent state of Katanga; and Albert Kalonji in south Kasai refused to obey Kasavubu or Gizenga. The original, centralized constitution was thus totally ineffective.

Tshombe was in a particularly strong position. Although the official Belgian forces had withdrawn at the request of the UN,

Tshombe's own troops were still led by Belgians and other foreign officers. He also had behind him the wealth of the province's mining resources and the support of the mining company Union Minière, and he knew he could rely upon the sympathy if not the active support of Belgium, Britain, and France. At the end of January 1961 Kasavubu, in an attempt to win over some of the other provinces, summoned a preliminary conference at which he called for a united Congo with greater autonomy for the regions. Unsuccessful, he again tried (Feb. 9) to demonstrate the republic's stability by forming a new government with Ileo, one of his strongest supporters, as prime minister. Any hope of a *rapprochement* was shattered upon news of Lumumba's death.

Several Congolese leaders met in Madagascar in March, and it was thought that some understanding had been reached between Ileo's government and Tshombe; there were hopes also of establishing friendly relations with Gizenga. Later Tshombe claimed that Kasavubu had betrayed the agreement reached in Madagascar by his willingness to cooperate with the UN. Tshombe was therefore arrested (April 26) on the order of Kasavubu's government and was detained until, after nearly two months, he agreed to reunite Katanga with the republic. Having safely returned to Katanga, however, he went back on his word and did not attend the assembly meeting in Léopoldville in July. Nevertheless, Kasavubu was able to name a new government, with Cyrille Adoula as prime minister.

In August UN forces attempted to undermine Tshombe's position by disarming Katangan soldiers and police. Tshombe resisted. Secretary-General Hammarskjöld was killed in a plane crash on Sept. 18, while on his way to meet Tshombe to try and reach an agreement. A cease-fire was agreed to on Sept. 20, but in November Mobutu launched an attack to try to end Katanga's secession. On Dec. 5 fighting broke out in Elisabethville between UN and Katangan forces; another cease-fire arranged two weeks later was followed by talks between Tshombe and Adoula.

This meeting, like several held in 1962, came to nothing owing to Tshombe's unwillingness to cooperate wholeheartedly with Adoula's government. Faced by an apparently endless deadlock, the acting UN secretary-general, U Thant, proposed a three-phase plan to reunite Katanga with the rest of the country. All taxes, duties, and mining royalties would be divided equally between Katanga and the central government, and the armies of Katanga would be united with those of the republic within two months. If this failed, U Thant proposed a trade ban on Katanga and finally, if all other measures proved unsuccessful, the UN command would be authorized to end Katanga's secession. Once again, however, Tshombe refused to cooperate, confident that he had the sympathy of some of the most powerful governments and financial interests in Europe.

In December 1962 UN forces undertook military action against Katanga. After initial stubborn military resistance, Tshombe's opposition suddenly collapsed and he agreed (January 1963) to give up his secessionist claims. The situation was still far from settled, however, for the UN forces were a heavy financial burden on UN revenues, and it seemed inevitable that operations would have to be curtailed. Continued opposition to Adoula in Parliament also presented the government with serious problems. Finally, on Sept. 30, 1963, Kasavubu dissolved the legislature and appointed a commission to draft a new constitution. On Oct. 1 Adoula's government was given full legislative powers. But its position was weak. The economy had never been worse; the army needed drastic reorganization; and the pro-Lumumbist critics of the government were untiring in their opposition. The UN therefore agreed to retain some forces in the country (the last troops withdrew on June 30, 1964). Kasavubu tried to deal with the financial situation by devaluing the Congolese franc. In March 1964 the constitutional committee recommended a new constitution that would reduce the powers of both prime minister and the assembly while increasing those of the head of state. But the referendum (June-July) that was claimed to have approved the new constitution was extremely suspect, and Adoula's new government was incapable of controlling the increasingly widespread disorders.

In July 1964 Kasavubu asked his old opponent, Tshombe, to form a government. This appointment alienated any sympathy that most of the African countries might previously have had for the problems of the central government, and Tshombe's appeals to them for military aid to face the rebellions organized by the anti-Tshombe elements met with no response. The United States sent arms and equipment, and this was followed by Belgian military intervention to rescue Europeans held as hostages by the rebels. In November 1964 U.S. aircraft dropped Belgian paratroops on Kisangani to help Tshombe's government recover the city, an action that aroused lively discussion throughout the world. This and other events of 1965, along with constant dissension among the rebel leaders, extinguished their hopes of victory.

Restoration of normal life was difficult, however. In parts of the country children were dying of a nutritional disease caused by lack of protein in the diet; the loss of crops as a result of the recent fighting caused hardship in the northeast and east; and re-opening of communications took place only slowly.

In the spring of 1965 elections to the national and provincial assemblies, though accompanied by administrative difficulties and irregularities, appeared to give a clear majority to Tshombe's Congolese National Convention (CONACO). But friction arose between Tshombe and Kasavubu, as a result of the latter's announcement that the time was not ripe for government by one party, and on Oct. 13 Kasavubu dismissed Tshombe and replaced him as prime minister with another Katangan, Evariste Kimba. Tshombe blocked confirmation of the appointment.

On Nov. 25, in a bloodless coup led by General Mobutu, Kasavubu was deposed. Mobutu proclaimed himself president and suspended certain constitutional provisions. In March 1966 he superseded the national assembly by assuming all national legislative powers, most of which, however, he reinstated in September, reserving the right of decree in periods of emergency. In June 1966 four former cabinet ministers, including Evariste Kimba, were hanged after being convicted of plotting to assassinate Mobutu. A revolt by Katangan military units in Kisangani in July was quickly put down, but a rebellious spirit continued to simmer among them. (K. I.; X.)

#### IV. POPULATION

The Democratic Republic of the Congo is one of the most sparsely populated countries in Africa. The total population was estimated in 1965 at 15,803,916 with an average density of 17.3 persons per square mile. The indigenous population was estimated at 10,353,900 in 1941 and at 13,540,182 in 1958; but in 1941 more than 91% lived in native settlements, in 1958 the proportion was 77%; thus by 1958 more than 3,000,000 Africans lived in towns or industrial areas, or on European plantations.

The European and nonindigenous population of the former Belgian Congo was over 100,000 in 1958, more than four times that in 1939, Belgians accounting for 76% of the 1958 figure. However, it showed a marked decline after independence.

Just within the mouth of the Congo is the harbour of Banana, the oldest trading station in the Congo, European merchants having been established there since the 16th century. On the north bank of the estuary is Boma (*q.v.*), formerly the administrative capital. It is the port of the Mayumbe country, with which it is connected by railway and road. Farther up the river and 93 mi. (150 km.) from Banana is Matadi, the farthest point reached by ocean-going ships and the port for most of the country.

From Matadi a railway runs past the cataract region to Stanley Pool, where stands Kinshasa (*q.v.*; formerly Léopoldville), the capital, with a population (1965 est.) of 503,432, of whom about 95% were African. About 750 mi. (1,200 km.) NE from Kinshasa is Kisangani (*q.v.*; the former Stanleyville), pop. (1960 est.) 126,533 (93% Africans). Roughly equidistant from Kinshasa and Kisangani, at the confluence of the Ruki and the Congo, is Mbandaka (formerly Coquilhatville; pop. [1958 est.] 36,156 Africans and 1,431 Europeans). Other main towns (pop. estimates) are Bukavu (formerly Costermansville), on Lake Kivu (28,960 Africans and 4,308 Europeans); Lubumbashi (formerly Elisabethville; 168,775 and 13,863); Luluabourg (St.

432 and 3,103); Mbuji-Mayi (formerly Bakwanga; 40,584); Albertville (29,488); Goma (11,221); and Jadotville (69,814 and 4,664). The former European sections of the principal towns have many of the conveniences of modern cities, including electricity, sanitary facilities, public water systems and running water, ice plants, well-built houses, good food supply, newspapers, hotels, cafes, social and sports clubs, and motion-picture theatres. The population of Congolese towns has considerably increased since independence.

## V. ADMINISTRATION

The administration under the Belgians was the responsibility of the minister for the Belgian Congo and Ruanda-Urundi. His representative in Africa was the governor-general, who was responsible for the conduct of the government, assisted by one or more deputy governor-generals. Each of the six provinces (Léopoldville, Équateur, Orientale, Kivu, Kasai, and Katanga) was directed by a governor, and each had its own distinctive character. The provinces were subdivided into districts and territories. Each territory comprised several native sectors or circumscriptions under an African chief, whether the traditional chief or one appointed by the administration. These chiefs tried certain offenses according to the customary law and were responsible for implementing

ceded to the republic in March 1964. In the first period after independence the lack of trained Congolese officers was one of the factors responsible for the army mutinies, the breakdown of discipline, and the subsequent political confusion. Following the refusal of certain African countries in August 1964 to send troops to assist the Congolese National Army in its fight against the rebels, white mercenaries were recruited for this task. Late in 1964 a program to rebuild the Congolese Army, involving Belgium (which would provide instructors) and the United States (which would pay for equipment and supplies), was begun.

## VI. THE ECONOMY

Under Congo Free State rule, no distinction was made between the state as administrator and as trader and landlord, whether the estates were worked directly or through concessionaires. Great efforts were made to obtain the maximum output of the two products most easily available—rubber and ivory—but the needs of transport and of bringing the country under control entailed the raising of large loans. During that period 75% of the revenue was derived from rubber and much of the remainder from ivory. Commercial prosperity subsequently came with the development of the extremely varied mineral wealth, and during the colonial period (1908–60) the administration consistently maintained favourable annual trade balances. The economic situation after independence was precarious, although a UN report of May 1964 noted "slow but perceptible progress toward recovery."

**1. Agriculture.**—Under colonial administration the abandonment of the compulsory collection of wild rubber by the Africans coincided with a fall in prices in Europe; later, plantation rubber from Malaya and the Netherlands Indies very largely supplanted wild rubber. While wild rubber continued to be collected to a diminishing extent, rubber plantations were started. Sugarcane planting began in 1926 in the region between Matadi and Stanley Pool and gave good promise; coffee cultivation, begun about 1920 in the Kivu and Uele districts, proved a success. Large palm-oil plantations were created by various companies, which also exploited the wild oil palms. Africans developed the cultivation of bananas, which were exported from Mayumbe, and also of peanuts and coffee. The Belgians introduced cotton cultivation in Katanga, Kasai, and the northern regions. Smaller amounts of pyrethrum, cinchona, tea, and perfume plants are grown. Subsistence crops are mainly cassava, maize (corn), rice, peas, bananas, sweet potatoes, yams, and beans.

Rough and dressed timber are exported in significant quantities. The most important timber-producing region is in Uele, especially Mayumbe and the area around Lake Léopold II. Veneer leaves and plywood are also produced. Cattle raising, undertaken first by settlers in Katanga, expanded rapidly in the 1920s and spread to the region of the great lakes, eastern Kasai, and the Lower Congo. Goats and sheep are also raised by Africans.

**2. Mining and Industry.**—The Katanga area (comprising, after 1966, the provinces of Nord- and Sud-Katanga), which produces large quantities of tin, also has uranium (and radium), manganese ore, and zinc, and ore sufficient to control the world's supply of cobalt. But it is chiefly famous for its copper and is the main source for hydroelectric power. In 1906 the Free State government granted to the Union Minière du Haut-Katanga a mining concession covering 13,000 sq.mi., effective till 1990. Katangan copper ores are concentrated and copper and cobalt are refined by electrolysis in plants operated by the Union Minière, utilizing power chiefly from hydroelectric plants at the Cornet Falls on the Lufira River near Jadotville, and on the Lualaba River. Katangan uranium oxide is exported to Europe and was an important source of supply to the U.S. in the 1940s and '50s.

Kasai is an important source of gem and industrial diamonds, produced by the mining company, a subsidiary of the Société Générale de Belgique. The chief centres of exploitation are Tshikapa and especially Mbuji-Mayi (formerly Bakwanga), the greatest world source of industrial diamonds. Tin, gold, and beryl are mined in the Kivu area, and gold in Kibali-Ituri. In February 1965 an agreement was negotiated between the Belgian government and the republic regulating the control of mineral production

*Political Subdivisions of the Congo\**

Province	Area (in sq.mi.)	Population (1965 est.)	Capital
Bandundu	115,455	2,365,745	Bandundu
Équateur	155,259	2,128,873	Mbandaka
Haut-Congo	77,053	769,907	Kisangani
Kasai-Occidental	100,890	1,250,511	Lulubourg
Kasai-Oriental	23,845	741,295	Mbuji-Mayi
Kibali-Ituri	25,351	945,119	Bunia
Kinshasa (Federal District)	763	503,432	Kinshasa
Kongo-Central	22,644	1,140,474	Songololo
Nord-Katanga	110,805	1,110,674	Albertville
Nord-Kivu	23,950	1,109,799	Goma
Sud-Katanga	81,073	986,628	Lubumbashi
Sud-Kivu	76,080	1,700,625	Bukavu
Uele	91,897	1,050,834	Isiro

\*After the provincial consolidation of 1966.

government decisions. Belgian rule, however, left the country with few able native administrators. By a law promulgated in August 1962, the number of provinces was increased to 21. Later, further reorganization took place. In 1966, by consolidation, the number of provinces was reduced to 13 (see table).

**1. Constitution.**—In May 1960, by the constitution (*Loi Fondamentale*) created by the Belgian Parliament, two legislative assemblies were established: a Chamber, whose members were elected in principle by direct universal male suffrage; and a Senate, whose members were nominated by the provincial assemblies, themselves elected by direct or indirect suffrage. The president was elected by both assemblies in joint session, requiring a two-thirds majority. He had power to appoint and dismiss ministers; any act of his required countersigning by the appropriate minister. This last provision was abolished by a new constitution favouring a strong presidential form of government, promulgated in August 1964. The constitution created a Constitutional Court, charged with verifying the legality of the president's election.

**2. Education.**—Education was for long in the hands of the Christian missions, and until the 1950s there was practically nothing except primary schools. The majority of missionary schools (about 20,000) were operated by Catholic missions and most of the remainder (about 9%) by the Protestant missions. State education was developed after World War II. No reliable school statistics were available in the 1960s. The republic has three small universities: the state university at Lubumbashi, the Lovanium Catholic University near Kinshasa, and the Free University of the Congo at Kisangani.

**3. Defense.**—The Congo possessed under the Belgian administration a *Force Publique* of more than 23,000 African noncommissioned officers and soldiers, with 990 European officers and noncommissioned officers. Belgium also equipped military bases at Kamina (in Katanga), Kitona (in the Lower Congo region), and a naval base at Banana (at the mouth of the Congo); these were

and transportation. Industrial and commercial products include cement, gunpowder and explosives, sulfuric acid, beer, peanut oil, margarine, textiles, leather shoes, cigarettes, bricks and tiles, bottles, metal and enamel containers, garments, and haberdashery.

**3. Foreign Trade.**—During World War II and after, exports exceeded imports. Machinery, fuels, textiles, and foodstuffs predominated in the imports, while minerals and agricultural products comprised the bulk of the exports. Prior to independence Belgium supplied more than one-third of the imports and took nearly half of the exports of the Congo, followed by the United States and the United Kingdom. In the 1960s Belgium remained the Congo's chief outlet for exports, but the United States had become the largest supplier of imports.

**4. Finance.**—The monetary unit is the Congolese franc (FC), nominally an independent currency and formerly at par with the Belgian franc, but on Nov. 9, 1963, devalued from FC 65 to FC 180 for U.S. \$1. The financial position of the country was satisfactory up till independence, and, especially after World War II, the budgets usually had surpluses. With independence, shortage of trained civil servants and haphazard methods of tax collection were persistent factors in an unbalanced budget. In addition foreign companies remaining in the Congo paid almost no taxes.

**5. Transport and Communications.**—By agreement the government gained control of all transport facilities in February 1965. There are 8,500 mi. (13,700 km.) of waterways (see CONGO RIVER), 3,000 mi. (4,800 km.) of railways, and 90,400 mi. (145,550 km.) of roads. A part of the rail system was designed as supplementary to the navigable rivers, which are often interrupted by cataracts and rapids. The Mayumbe railway connects the port of Boma northward with Tshela in the forest region, and a line runs from Matadi to Kinshasa. From Port-Franqui the rails run southeastward, serving Luluabourg, Kamina, Bukama, Tenke, Jadotville, Lubumbashi, and Sakania; south of Sakania they link with the Zambian railway. Another line of trackage, beginning at Kindu on the Upper Congo, bypasses rapids and leads southward to Kabalo, Kamina, and Tenke. From Tenke another line runs westward to Dilolo, near the Angola frontier, where it connects with the Benguela Railway and thus with the Portuguese Atlantic port of Lobito. A line from Kabalo to Albertville, on Lake Tanganyika, connects the Congo by lake traffic with the railway to Dar es Salaam, on the Indian Ocean. In the north, a line runs from Aketi to Isiro (former Paulis) and Mungbere.

Four ports are accessible to ocean steamers: Banana, Boma, Ango Ango, and Matadi. Matadi is the main port; Ango Ango, nearby, serves as a petroleum port. Lobito in Angola is an important outlet for Congolese exports. The airports at Kinshasa, Kisangani, and Lubumbashi have international connections (principally via Brussels and Johannesburg), and internal routes are operated by Air Congo, the national airline.

Radiodiffusion Congolaise at Kinshasa, with regional stations at the main centres, broadcasts in French and Congolese.

## CONGO FREE STATE: see BELGIAN CONGO.

**CONGO RIVER**, the second longest river in Africa, its length of 2,716 mi. (4,371 km.) from the source of the Chambezi in Zambia to its mouth at Banana (Banane), Democratic Republic of the Congo, being exceeded only by that of the Nile, 4,157 mi. (6,690 km.). The Congo's drainage basin, with an area of about 1,425,000 sq.mi. (3,690,750 sq.km.), and its mean discharge (into the Atlantic) of 1,400,000 cu.ft. (39,644 cu.m.) per second are,

however, much greater. Its vast basin lies astride the equator in west central Africa, and it includes almost the whole of the Democratic Republic of the Congo, most of the Congo Republic, the western part of Zambia, and the northern part of Angola.

In both the Congo republics the main stream and its tributaries are valuable commercial waterways; they were of first importance in opening up an enormous region that was largely unknown to Europeans until the end of the 19th century. But the inland waterways are cut off from navigation to the Atlantic by the Livingstone Falls, where the river drops 886 ft. in 215 mi. (270 m. in 346 km.). Materials are carried inland to Stanley Pool above the falls by two railways. One, constructed by the French, runs from Pointe-Noire to Brazzaville; the other, built by the Belgians, links Matadi at the head of the Congo estuary to Kinshasa (formerly Léopoldville).

**Congo River System.**—The headstreams of the Upper Congo flowing north from the plateaus of northeastern Angola and Katanga include the Lualaba in the east; this is usually regarded as the Congo main stream. It receives tributaries flowing west from the high plateaus of Zambia and western Tanzania (Tanganyika) and from the highlands bordering the western section of the Great Rift System and leads their waters by a great arc north of the equator to Stanley Pool and then via a narrow gorge across the Crystal Mountains to the Atlantic. It is joined by several other great rivers in the Middle Congo Basin, notably the Ubangi (q.v.) bringing the waters of the area to the north, between the Cameroon highlands and the region west of Lake Albert, and the Kasai River (known as the Kwa in its lower course) draining the southwestern part of the basin.

Because of the distribution of its tributaries on both sides of the equator, the Lower Congo is well supplied with water at all seasons. In July, when the flow of the southern tributaries dwindles, the northern tributaries are flowing strongly; in January the position is reversed. The ratio between the mean maximum discharge of about 2,500,000 cu.ft. (70,800 cu.m.) per second and the mean minimum flow of about 800,000 (22,600) is unusually low, especially for an African river.

**Upper Congo.**—The easterly headstreams are generally regarded as marking the true course of the river. The most remote of these is the Chambezi, which rises in the highlands between Lakes Nyasa and Tanganyika and flows southwest across the gently sloping plains of Zambia. After skirting Lake Bangweulu it is known as the Luapula. Already it is a large river with a mean discharge at the Girard Falls of 2,000 cu.ft. (57 cu.m.) per second and a flood discharge of ten times that amount. For 300 mi. (480 km.) it defines the frontier between Zambia and the Democratic Republic of the Congo. Below the Johnston Falls it is navigable for small boats for 100 mi. to Lake Mweru (q.v.). On the shallow lake, traffic is impeded by papyrus and other swampy plants, and farther downstream the river, known as the Luvuvu, is interrupted by falls. These were harnessed 30 mi. above Kiambo at Piana-Mwanga to generate electricity for the mines at Manono and Kitotolo. Below the falls the river is navigable for 100 mi. to its confluence with the Lualaba at Ankoro.

The Lualaba rises near Musofi at about 4,600 ft. (1,400 m.) and descends rapidly to the Biano Plateau where it flows across an ancient lake bed at about 4,000 ft., most of which is under cultivation. It cuts deeply into the plateau edge to form the narrow gorges of Zilo and in 45 mi. descends 1,500 ft. to the floor of the Kamolondo trough. The mean discharge of the river is more than 3,000 cu.ft. (85 cu.m.) per second and the drop is utilized at the Delcommune Falls where electric power is generated on a large scale. To maintain the flow, a dam 215 ft. high was built above the falls to hold up a lake covering 39 sq.mi. (101 sq.km.).

The Kamolondo trough, like the depression where Lake Mweru lies, is the outcome of downfaulting in late geologic times. The gradient of the river is gentle, and downstream from Bukama it is navigable for 400 mi. Several large lakes occupying the floor of the trough are linked by channels to the Lualaba; the largest of them, called Upemba, receives the waters of the Lufira River. Rising south of Jadotville the Lufira was dammed below the town to form a lake with an area of 160 sq.mi. to provide storage

CONGO RIVER BASIN

for a power station on the Cornet Falls. Traces of an ancient lake bed remain where it skirts the Kundelungu Mountains below Lukasu. At the Kuibo Falls the Lufira descends more than 100 ft. and traverses the Bia Mountains in a deep gorge to join the Lualaba via Lake Upemba. Navigation farther down the Lualaba is hindered by papyrus and floating islands of vegetation where the river widens out to form Lake Kisale, and the expense of maintaining a channel there, 150 ft. wide and 5 ft. deep (46 by 2 m.) is considerable. The river route on the Upper Lualaba is duplicated by the railway from Kamina to Kabalo.

Below Kongolo the Lualaba has cut a very deep gorge, in places less than 100 yd. wide, called the Portes d'Enfer. A concrete bridge carries the railway from Kindu to Albertville across the gorge. This line follows the valley of the Lukuga, the river linking Lake Tanganyika (q.v.) and its catchment to the Lualaba. For a stretch of 68 mi. downriver from Kasongo the river is again navigable, but more rapids and waterfalls interrupt its course at Kibombo. Below Kindu the river flows between rocky bluffs 50 to 60 ft. high, and in periods of low water its depth is reduced by rock bars to about 3 ft. Nevertheless it is utilized by boats for 190 mi. between Kindu and Ponthierville where the Stanley Falls

commence. Seven cataracts, extending for 60 mi. along a great westward curve of the river and giving a total fall of about 200 ft., are circumvented by rail and road by which goods are carried between Ponthierville and Kisangani (formerly Stanleyville), at the head of navigation on the Middle Congo. Stanley Falls mark the end of the Lualaba and the beginning of the Congo proper. Below Kisangani the Congo becomes sluggish and is unbroken by rapids for more than 1,000 mi.

**Middle Congo.**—From a width of about half a mile at Kisangani the river widens to more than a mile and its banks decline in height as the confluence with the Lomami is approached. At Isangi the Congo enters that central part of its basin occupied several thousands of years ago by a great shallow lake. The bed widens and near the mouths of tributaries its banks are as much as 9 mi. apart. The average width is about 4 mi. and navigation is limited in February, July, and August to boats drawing less than 5 ft. of water. The shifting channels threading between sandbanks have been buoyed, and with dredging it is usually possible to maintain a passage six or seven feet deep. After crossing the equator at Mbandaka (formerly Coquilhatville), the river is joined by the Ubangi, which forms a delta 9 mi. wide; the delta concealed from the explorer H. M. Stanley the fact that this was the confluence of the Congo and its largest right-bank tributary.

Farther downstream the river is littered with sandbanks and large islands and spills over its low banks to flood flat forested country on both sides for distances of 5 or 6 mi. Its average

slope remains less than five inches to the mile, and for 300 mi. down to Stanley Pool boats drawing ten feet of water can operate throughout the year. Near Lukolela the Sanga River enters from the north and provides access to the Cameroons. At Bolobo the river narrows to less than 1½ mi.; rock outcrops on the floor of Sandy Beach Pool, and immediately downstream the Channel begins. There the Congo for 125 mi. is only a mile wide and overlooked on either hand by steep sandstone bluffs. It runs 100 ft. deep and even more near Kwamouth where the waters of the Kwa (Kasai) enter the main stream. Suddenly the steep banks decline and the Channel widens out into Stanley Pool, a shallow lake 22 mi. long and 14 mi. wide, with deep navigable channels leading either side of Bamu Island to the ports of Brazzaville (q.v.) on the north shore and Kinshasa (q.v.; formerly Léopoldville) on the south; these are the terminals of inland navigation.

**Lower Congo.**—At the western end of the lake, the waters of the Congo topple over a rocky sill, and from a height of 908 ft. (277 m.) at Stanley Pool the river drops to 630 ft. (192 m.) at Manyanga over a distance of 83 mi. (134 km.). Beyond the pool begin a series of 32 cataracts known collectively as the Livingstone Falls which extend between Kinshasa and Matadi. The tributaries

from the Crystal Mountains to the north and south enter by high falls, and electricity is generated at the Sanga Falls on the Inkisi for Brazzaville and Kinshasa. For 87 mi. to Isangila, relatively weak calcareous schists outcrop and there are only a few minor rapids. Then more very tough rocks form a barrier and the river falls from 560 ft. to 25 ft. near Matadi at the head of the estuary. At the Inga Falls, about 25 mi. above Matadi, the potential power has been estimated at 25,000,000 to 30,000,000 kw.

Matadi, standing a little way downstream of the lowest falls on the river, has one of the largest ocean harbours in central Africa. Its waterfront, cut out of granite, is about a mile in length. Growth of the town is restricted by the steep hills overlooking the river. In the upper estuary the Congo has cut a channel more than 100 ft. deep into solid rock, and although the current is generally no more than three or four miles per hour, there are several turbulent passages of which the best known are the violent eddies and whirlpools of the Chaudron d'Enfer below Matadi. Below Fetish Rock the river opens out into a pool 12 mi. wide, but near Boma sediment has accumulated to form several islands and the channel has to be dredged to allow ocean-going vessels to reach Matadi. At Boma (*q.v.*) the tidal range is less than a foot, compared with about six feet at the seaward end of the estuary, 92 mi. below Matadi. In this seaward section downstream of Boma mangrove swamps cover recent sediments along the shore, but the central channel cuts down very deeply.

At the mouth, between Pointe Padrao on the south and Pointe de Banane on the north side, where the river is 6 mi. wide, soundings of 1,450 ft. have been obtained, and the course of the Congo is prolonged offshore as a submarine canyon cut in places 4,000 ft. below the level of the surrounding sea floor. So great is the discharge of the river that brownish-coloured fresh water lies at the surface about 50 mi. from the coast, and the Congo waters can still be distinguished by their olive-green colour more than 300 mi. out to sea.

**The Congo as an Inland Waterway.**—The Congo and its tributaries form a magnificent system of navigable waterways, and nearly 8,000 mi. of river routes are in regular use in addition to the lake routes on Kivu, Tanganyika, and Mweru. The non-navigable sections are bypassed by railroads (Matadi-Kinshasa, Kisangani-Ponthierville, Kindu-Kongola). Port-Francqui on the Kasai River is an important transshipment point for Katanga copper ores and the terminus of the railroad from Bukama. Tugs, barges, and other boats comprising about 500,000 tons of shipping make connections between the various railroad and highway systems serving the interior. The larger boats were formerly stern-wheelers, fired by wood and drawing about three or four feet of water, but following Mississippi experience, boats propelled by diesel engines were introduced along with tugs designed to push trains of barges carrying thousands of tons of cargo. Illuminated buoys allow movement by night, and some ships carry radar.

In the 1950s the water hyacinth *Eichornia crassipes* appeared on the Congo and spread with remarkable speed to form a serious obstacle to navigation. The plant invaded all the banks of the river and several tributaries, including the creeks between the islands in the main stream. It has become necessary to treat thousands of square miles to eradicate the plant.

**Hydroelectric Power.**—The floor of the Congo Basin stands for the most part more than 1,000 ft. above sea level. More than half of the basin is at 1,500 to 3,000 ft. and about a quarter is above 3,000 ft. Combined with the high rainfall (50–70 in. [1,270–1,778 mm.]) over the basin and consequent great discharge of the river, this high elevation makes the Congo an enormous potential source of water power. Of the total potential, which probably exceeds that of the United States, only a small fraction had been harnessed by the 1960s. Development had been confined mainly to the Katanga mine fields region, but it expanded rapidly in many centres after mid-20th century due to an apparent lack of oil or good quality coal as alternate sources of power.

**The Evolution of the Relief of the Congo Basin.**—The ancient rocks of Africa outcrop round the rim of the Congo Basin; they form the mountains on either side of the Livingstone Falls; they build the Cameroon highlands and underlie the lower coun-

try north of the Ubangi and Uele rivers. In the eastern highlands they have been let down between faults and thrust up as horsts. In Katanga they are highly mineralized and yield copper and other ores. Among the Precambrian sedimentary rocks are formations of glacial origin, and in the southeastern highlands traces persist of a much later Upper Carboniferous mountain glaciation. Geomorphological measures accumulated in Permian times, and toward the end of the Paleozoic Era the rocks give indication of increasing aridity. Continental sediments accumulated in Mesozoic times, but there was at least one marine incursion in the Jurassic Period when the sea probably spread across from the Indian Ocean. Later, in Cretaceous times, marine sediments were laid down both along the coast and in the interior basin.

The evolution of the relief and drainage pattern in most areas is still the subject of speculation. Research in the southern part of the Democratic Republic of the Congo appears to provide a basis for establishing a chronology for much of southern Africa. A great deal of the basin is characterized by extensive, gently sloping, dissected plateaus, separated from each other by escarpments and with the falls in the rivers corresponding to the escarpments and to the outcrop of resistant beds of rock. These plateaus are covered in places by sediments. They appear to be the outcome of successive periods of planation following rejuvenation of the rivers as a result of repeated uplift of the basin as a whole.

The northward-flowing streams of the Kasai System may once have drained to the Chad Basin, and the Ubangi above the Zaire Rapids may have continued to flow in that direction until quite a late stage. The Lualaba and its tributaries above the Port d'Enfer probably belonged in Tertiary times to the Nile System and ran into the Indian Ocean. A great lake developed in the central basin as a result of downwarping toward the end of the Pliocene Period and this was later drained into Stanley Pool. The Livingstone Falls on the river's lower course are undoubtedly youthful.

**Vegetation and Animal Life.**—The central parts of the basin, between 4° N and S of the equator, experiencing a heavy rainfall and only a short dry season, are largely covered with the great trees and lianas of rain forest, which is often marshy and always humid. To the north of Ubangi and to the south of the lower Kasai the rainfall diminishes and becomes more seasonal, and although tall gallery forest persists along the waterways the interfluvies are covered with savanna woodland. Leguminous species are abundant, especially in the south, and toward the drier margins of the basin thorny acacias predominate. As the altitude increases, the savanna trees diminish in size and number, and above 5,000 ft. the uplands are largely grass-covered and provide good pasturage. At still higher levels the vegetation is characterized by bamboos, and near the crests of the mountains bordering the western Great Rift Valley appear strange treelike heath-like lobelia, and giant senecio.

In spite of the low population density over most of the Congo Basin, the vegetation has been altered over very wide areas by cultivation and burning and in such areas as the mine fields of Katanga few traces of the original plant cover remain. Many cultivated plants have been introduced from other parts of the world: cassava, corn (maize), and several others were brought from South America by the Portuguese; others, such as sugarcane and citrus trees, are of oriental origin.

The fauna is exceedingly rich and is of great interest because many species persist in the Congo Basin which have been eliminated from more heavily settled parts of the continent. Some animals such as elephant and leopard are found in both savanna and forest in most parts of the basin, but the distribution of many species is related to the vegetation pattern. Lion and zebra, for example, are confined to the grassy savannas in such areas as the upper Uele and Katanga; gorilla live in the bamboo forests of the mountains. During the Belgian colonial era many of the rarer animals such as the rhinoceros, okapi, and zebra were protected and could not be shot; licences were required to hunt several others. In reserves and in national parks, such as Upemba, hunting was completely prohibited. More than 1,000 species of fish have been identified from the waters of the Congo System; among the best known is the lungfish *Protopterus*, which may weigh 100 lb.

**Exploration.**—In contrast to the Nile, there are practically no classical associations with the Congo, and except for its estuary the river remained unknown until the journeys of David Livingstone and H. M. Stanley (*q.v.*) in the latter half of the 19th century. The Portuguese Diogo Cam (*q.v.*) discovered the mouth of the river in 1482 and erected a marble pillar on the left bank. The river was first called Rio del Padrao (Pillar River), but it soon became known as Zaire, corrupted from the native name *Zadi*, meaning "great water." Colonies were founded on the banks of the Lower Congo by the Portuguese, and in the 16th century a kingdom with its capital at São Salvador in Angola flourished on the left bank of the river. Portuguese visited this colony regularly, and in 1591 Duarte Lopez published the story of his travels. After 1627, when Europeans were expelled from the kingdom, little was done to explore the river until the British Admiralty dispatched Capt. J. K. Tuckey at the head of a well-equipped mission in 1816. Tuckey managed to push up the Congo as far as Isangila beyond the lowest series of rapids, but sickness broke out and the commander and 16 other Europeans died. For 60 years no other Europeans reached even as far as Isangila. Tuckey's expedition had been prompted by the suggestion that the Congo was identical with the Niger, but a few years later Hugh Clapperton's expeditions to the Western Sudan made this seem unlikely, and eventually the Congo System was mapped by explorers working down from its headstreams. Following in the tracks of Arab traders based on Zanzibar, Richard Burton and J. H. Speke (*q.v.*) reached Lake Tanganyika (1857–59). David Livingstone had already crossed the headstreams of the Kasai and Kwango in the early 1850s, and in 1868, having explored Lake Nyasa, he entered the Congo Basin, discovering the Chambezi and Lake Bangweulu. In March 1871 he reached the town of Nyangwe on the Lualaba which was also reached by V. L. Cameron (*q.v.*).

Livingstone died (1873) while endeavouring to trace the headstream of the Lualaba, which he believed to be the Congo. "I have no fancy," he once said, "to be made into 'black man's pot' for the sake of the Congo." But by 1872 geographers were able to affirm, from Livingstone's own reports, that the great river system he had explored must belong to the Congo and not to the Nile. In 1876 Stanley arrived at Nyangwe from Zanzibar, and, having assembled the boat that was carried overland from Zanzibar and having bought 20 canoes, he navigated the river more than 1,600 mi. to Isangila. Stanley's great journey had demonstrated the identity of the Lualaba with the Zaire of the Portuguese and had provided the key to the opening up of the interior. His services were enlisted by Leopold II of Belgium, and in 1880–82 he opened up a road to link the estuary of the Congo at Viva, opposite Matadi, to Léopoldville and built a steamer, the "Forward," to sail on Stanley Pool.

Further explorations continued, and George Grenfell (*q.v.*) did much to add to the exact knowledge of the river and its tributaries. At the time of the expedition in search (1887–89) of Mehmed Emin Pasha (*q.v.*), Stanley visited the Aruwimi and Ituri; in the same years the Ubangi, Mongala, and Uele were traced; four successive expeditions explored the southern part of the basin, under the leadership of P. Le Marin in 1890–91, W. G. Stairs in 1891, A. Delcommune in 1891–93, and E. Bia-Francqui during the same period. Detailed mapping of the basin continued, making the most rapid progress in areas with important mineral resources. The Congo Basin is discussed further in *AFRICA: Physical Geography*; CONGO, DEMOCRATIC REPUBLIC OF THE; CONGO (REPUBLIC); BELGIAN CONGO. See also references under "Congo River" in the Index.

**BIBLIOGRAPHY.**—The Tourist Bureau of the Belgian Congo and Ruanda-Urundi (ed.), *Traveler's Guide to the Belgian Congo and Ruanda-Urundi*, Eng. trans. by Jan-Albert Goris (1951); *Encyclopédie du Congo Belge*, 3 vol. (1951); M. Robert, *Le Congo Physique* (1946–48); Musée Royal du Congo Belge, *Congo Belge, Rapports Annuels*, section *Géologie, Minéralogie et Paléontologie*; Congo Belge et Ruanda-Urundi *Mémoire Service Géologique* (1951– ); Académie Royale des Sciences d'Outre-mer, *Atlas Général du Congo*. (A. T. Gr.)

**CONGREGATION**, an assembly of persons, especially a body so assembled for religious worship, or habitually attending

a particular church, and hence the basis of the religious system known as Congregationalism (*q.v.*).

**Old Testament and Judaism.**—Although the word congregation occurs more than 350 times in the King James version of the English Bible, only one of these occurrences is in the New Testament (Acts xiii, 43). All the other instances of the word are renditions of Hebrew words, of which the two most important reflect the ambiguity in the concept "congregation": one of the Hebrew terms refers to the entire Israelitic community, the other refers to the gathering or assembly of the people. Thus "congregation" means either a group of persons gathered for public worship or a permanent religious and social institution. In modern Judaism the term is sometimes used as an equivalent of the postbiblical Hebrew word *knesset* in its religious sense (the word *knesset* is applied also to the Israeli parliament).

**Roman Catholicism.**—In the Roman Catholic Church the word is used in several senses: (1) The congregations or committees of the College of Cardinals which form administrative departments; e.g., the congregations of Propaganda, Rites, etc. (2) The committees of bishops for the regulation of procedure at general councils. (3) Branches of a religious order, following its general rule but forming separate groups, each with its special constitution and observances; congregations of Benedictines, for example, include the Cassinese and the various national congregations. (4) Communities of religious under rule, composed of persons who have taken simple rather than solemn vows, such as the Passionists and Redemptorists (see *ORDERS AND CONGREGATIONS, RELIGIOUS*). (5) In France, religious associations of lay persons, male or female, for some pious, charitable or educational purpose.

**Protestantism.**—Protestant usage reflects the ambiguity of the King James version. A congregation usually means the assembly of worshipers gathered in a church at a particular service. But among English Nonconformists and American Protestants the term has been increasingly confined to the local church, often only to the lay people of the local church. In 1815–16 John Pickering, an early student of American linguistic usage, reported that "a church, as a body of persons . . . is distinguished in New England from a congregation, by the privileges which the former in general reserve to themselves of receiving exclusively in that church the sacrament and baptism. . . . Marriage, burial and public worship are open to the members of the congregation at large." The broadening of the standards for church membership in denominations of the Congregational tradition has tended to make even this distinction obsolete, and in America "congregation" has become virtually synonymous with "parish." (J. J. Pn.)

**CONGREGATIONALISM** is the name given to that type of Christian churchmanship and church organization found in churches generally now called Congregational, but also called Independent (as in the 17th century in England, and in Wales today), and also in some churches not carrying either name or historically connected with the origins of the denomination in England.

As a method of church organization Congregationalism emphasizes the autonomy of the local church and the voluntary fellowship of such churches for counsel. It regards church authority as inherent in each local body of believers, as a miniature realization of the whole church, which can itself have only an ideal corporate being on earth. It holds this concept of polity to be based on the New Testament and conceives its own contribution to the church universal as consisting in witnessing to this concept. But it also affirms the necessity of voluntary fellowship with other churches. Congregationalism thus differs from pure Independency by reason of this emphasis on both local autonomy and the fellowship with all the other churches of its order. Besides, it acknowledges itself to be part of the church universal. Hence, Congregationalism stands for that kind of polity which regards as churches only the local congregations of the church universal. Christ is the sole head of the church universal; this church is composed of local congregations, each of which possesses independence, but is united with others by a voluntary tie of fellowship.

This method of church government is derived from the fundamental principles of Congregationalism: the immediacy of the relationship between the believer and God, the gathered church as a covenanted fellowship under the lordship of Christ and the priesthood of all believers. These principles, held throughout all differences, indicate the true character of Congregationalism, which cannot be wholly understood merely as a form of church organization.

Congregational churches in recognized unions or associations are to be found in Argentina, Australia, Brazil, British Guiana, England, Finland (as the Free Church), Ireland, Jamaica, the Netherlands (as the Remonstrant Brotherhood), New Zealand, Scotland, South Africa, Sweden (as the Mission Covenant Church), the United States and Wales (both as part of the Congregational Union of England and Wales, to which the English-speaking Welsh Congregational churches belong, and as the Welsh Independents, who are Welsh-speaking). All these churches are united in a free association known as the International Congregational council with headquarters in London. With these churches are associated also a number of United Churches which contain former Congregational elements—in Canada, north India, south India, Japan and the Philippines. Missionary service in many parts of Africa, in Ceylon, Hong Kong, India, Malaya, Micronesia, Papua, the South seas, Syria and Turkey extends the number of those within the Congregational fellowship. The total number of communicant members, excluding those in united churches and in mission churches, in the mid-20th century was about 2,100,000. The four largest groups were in the U.S. (1,432,000; United Church of Christ, 2,000,000), England and Wales (212,000; Welsh Independents, 118,000) and Sweden (98,000).

## HISTORY

### ENGLAND

**Origins.**—Though the name "Congregational" was not in general use before the 1640s, the movement had its roots in the Reformation. It is no coincidence that the title of one of Congregationalism's foundation documents was Robert Browne's *A Treatise of Reformation Without Tarrying for Anie* (1582).

The main effect of the Reformation in England was that ordinary people were able to read or hear the Bible in their own tongue without fear of persecution. It was not long before men of sensitive spirit began to feel themselves invited to share in biblical religion and enter into biblical experience. Such men tended to grow impatient with what seemed to them the more complacent, conventional religion of the dominant party in the Established Church. Some hoped to bring the church to fuller reform from within. Others felt driven to break away from the Church of England and its subservience to prelate, parliament and magistrate, and to form new groups in which they could be free to worship according to their consciences.

All these men, whether remaining within the Church of England or not, were nicknamed Puritans because they passionately desired purity in worship, church government and personal life. Those who left the Church of England were also called Separatists. Christians, they held, were called by God to separate not only from the world but also, if necessary, from the church, if the church had become worldly. They called the new groups which they formed "gathered churches"—that is, societies of men and women who knew and manifested the gifts and graces of God's Spirit, and were called out by God to be separate.

The separatist principle and the voluntary principle were at the same time revolutionary and determinative of Congregationalism. Its founders were united in a recognition of the true inwardness of religion. "He is a christian which is redeemed by Christ unto holiness and happiness for ever and professeth the same by submitting himself unto his lawes and government," as Robert Browne says in his *Treatise*, and the church is made up of such Christians. The church is thus defined in terms of the believers of whom it consists, and without whom and whose active and professing belief, and whose consequent and evident holiness, it cannot exist.

Congregationalism may thus be seen as one of the earliest

attempts in England seriously to work out ecclesiological meaning of the Reformation doctrine of the priesthood of all believers, and to give due weight to the recovery at the Reformation of the sense of immediacy in the relation between the soul and God. That is not to say that the early Congregationalists were isolationists. On the contrary, they rediscovered much of the reality and glow of the New Testament *koinonia* ("communion" or "fellowship"). They were called Independents because they claimed independence of outer control—ecclesiastical control, whether by bishop or presbytery, no less than secular—but they sought such independence only in order to become more fully dependent on the Lord's will made known to them in fellowship. They came to be called Congregationalists because they claimed the right of all members of the congregation to a share in the direction of the church's affairs; but they claimed this as a right, because they saw it as a duty and privilege as they met together in the Spirit of Christ.

**First Hundred Years.**—Persecution by the dominant majority stimulated the elaboration of Congregational principles. This came in four waves of repression issuing from Lambeth during the primacies of John Whitgift, Richard Bancroft, William Laud and Gilbert Sheldon. The outstanding figure in the first was Robert Browne (*q.v.*), who, however, after much suffering, renounced his Separatist principles and conformed, though three of his contemporaries, Henry Barrowe, John Greenwood and John Peay (*qq.v.*), were martyred.

In the second period the most noteworthy was John Robinson (*q.v.*), who went into exile at Leiden, where he was pastor of the church some of whose members in 1620 sailed to New England in the "Mayflower." His writings include *A Justification of Separation* (1610), but he was anxious to distinguish those associated with him from the Brownists and Barrowists, and at the end of his life became less extreme in his separatism. John Cotton (*q.v.*) who in 1633 likewise went to New England, wrote in defense of Congregationalism *The Keyes of the Kingdom of Heaven and the Power Thereof* (1644). His path is described in the introduction to the *Keyes* by T. Goodwin and P. Nye as "that very Middle-way between what is called Brownisme, and the Presbyterian government."

In the turmoil of the English Civil War and still more under the protection of the Commonwealth legislation, Congregational churches sprang up in considerable numbers and with full conviction of their voluntary and separatist principles. The Independency of the Commonwealth was of a radical and self-assured type conscious of its difference from the Presbyterianism which for a time had been established in England and still flourished in Scotland. In Sept. 1658 the elders and messengers of the Congregational churches met in the Savoy palace and issued a *Declaration of the Faith and Order owned and practised in the Congregational Churches in England* (see CONFESSIONS OF FAITH, PROTESTANT). It was a bold manifesto, but less radical than English practice, for its admission of occasional synods does not seem to have been followed.

Under the novel and experimental ecclesiastical establishment set up by Oliver Cromwell about 130 Congregational ministers accepted parochial livings. The number is a small proportion of those who were ejected at the Restoration, for these numbered more than 1,900, but it is remarkable that there were any at all.

The Congregationalists were now consolidated and were able to endure the repressive measures which followed the Act of Uniformity in 1662. There was no fresh large-scale emigration. The outstanding name in this period, as indeed already during the Commonwealth, was that of John Owen (*q.v.*), who had been converted to Independency by Cotton's *Keyes* and was thus in sympathy with the less extreme kind of Congregationalism.

**18th Century.**—The passing of the Toleration act in 1689 and the death of Queen Anne in 1714 saw the end of persecution though not of severe restrictions. The exclusion of Nonconformists from the universities led, however, to the establishment of academies by means of which a liberal education was provided, better in many instances than that given at that time at Oxford and Cambridge. The leaders of the academies trained many learned men.

chiefly for the ministry. From them a number of the Congregational theological colleges take their origin. The academies made a considerable contribution to English culture.

The beginning of the century was marked by a growth in the building of meeting houses, but in other ways Congregationalism declined. Earlier convictions were lost. *An Enquiry Into the Causes of Decay of the Dissenting Interest* (1730) gives as the primary cause "ignorance of their own principles." Almost the only shining light in this period was the introduction of a new type of hymnody by Isaac Watts and Philip Doddridge.

Arid theological discussion, the spread of deism and a general love of pleasure and desire for riches were distinctive features of a long period of the 18th century. Congregationalism was rescued by the evangelical revival which affected Nonconformists perhaps more than any other religious body. The preaching of George Whitefield in particular led to a quickening of the spirit and a growth in the number of churches. The sense of Christ's presence within the local church was recaptured. Lay preaching became common. The hymns of Charles Wesley added a new warmth to worship. A new concern was born for evangelization at home and abroad. Sunday schools and a concern for social service were also part of its expression.

**19th Century.**—The new passion for evangelization overseas led to the formation of the London Missionary society in 1795. Undenominational in its beginnings and designed to leave converts "to assume for themselves such form of Church Government as to them shall appear most agreeable to the Word of God," the society became increasingly the vehicle for Congregational service and witness. Missionary enterprise was not started without some criticism, but the society gradually grew and won confidence, and its work extended until it was responsible for large areas in Africa, China, India and Madagascar, as well as for Papua and the South seas. It remains independent, but receives practically all its support from Congregationalists. Its roll of honour includes Robert Moffat and David Livingstone in Africa, Robert Morrison in China and John Williams and James Chalmers in the South seas.

In 1836 a definitely Congregational society was formed to meet the needs of the thousands leaving Britain to settle in the colonies. The Colonial (later Commonwealth) Missionary society established Congregationalism in Australia, New Zealand, Canada and South Africa. It continues to care for emigrants, though its principal concern is for the Congregational churches of Jamaica, British Guiana and South Africa, originally fields of the London Missionary society.

Before the 18th century closed, itinerant societies had been formed among the churches for local evangelization. In many districts ministers, and in some cases churches, had begun to form associations "to promote mutual edification by Christian and ministerial intercourse, and to diffuse plans for the spread of the Gospel." Numerous attempts were made to form the churches and county associations into a national union, but there was fear of central organization, and some held that Independency's glory lay in not being a denomination at all. But the movement for union was too strong to be resisted. The churches were growing in numbers; by 1830 there were probably about 1,600 of them. The *Congregational Magazine*, a monthly founded as the *London Christian Instructor* in 1818, was helping to instill a denominational consciousness, while co-operation in missionary work overseas encouraged similar co-operation at home. The need for some method whereby the stronger churches could help the weak was becoming urgent.

The success of the county associations commended a larger union. Finally the Congregational Union of England and Wales was formed in May 1831. All suspicions were overcome and the union became firmly established. At first it attempted too much in its eagerness to show what could be accomplished through co-operation. It sponsored missions in the colonies, in Ireland and at home, and established a board of education, a Chapel Building society and an Insurance Aid society. It assumed responsibility for two periodicals. The strength of the organization was not sufficient for all these activities, and in 1857 the union severed itself from the affiliated societies and the magazines. Later, when

its position was more assured, it began to gather the threads into its hands again. In particular it assumed responsibility for church aid and home missionary work. For this and for the growing responsibilities it accepted for the churches and for their ministers it raised considerable funds—notably the Central fund of £250,000 (1909) and the Forward Movement fund of £500,000 (1921), ministerial support and pensions being their primary purposes.

The increased activity of the union and the raising of these funds provided a supreme test for Congregationalism. It was not easy to reconcile the full independence of the local church with organized and official support and the necessary controls. An element of tension continued to be felt in the 20th century, but in particular situations it was repeatedly resolved. The union has neither sought nor been given final or absolute authority over the churches. At the same time the churches have given increasing powers to the union and have looked to it more and more for leadership and aid.

Because they were concerned for civic and religious liberty, Congregationalists, like other Nonconformists, became associated with all public movements to achieve them. Outstanding in the struggle for the rights of Nonconformists was the Congregationalist Edward Miall. The Test and Corporation acts were repealed in 1828, church rates abolished in 1868 and Oxford and Cambridge universities compelled to open their doors to Nonconformists. Congregationalists also began to wake up to social evils, and were active in securing measures for the extension of franchise, the abolition of slavery and the repeal of the corn laws.

From 1832 to the home rule split in 1886 Congregationalists were generally to be found supporting the Liberal party, which almost exactly expressed their political views. But the split divided the denomination, which did not again find a political party which fully represented its ideals and policy. The question of national education greatly concerned Congregationalists from the 1830s to the controversies of the beginning of the 20th century. In this period a well-remembered name is that of Charles Silvester Horne, a minister in London, member of parliament and passionate lover of freedom.

The closing years of the 19th century found Congregationalism rich in outstanding preachers, such as R. W. Dale, Joseph Parker, J. A. Macfadyen, Alexander Mackennal; theologians such as Andrew Fairbairn and P. T. Forsyth; administrators and ecclesiastical statesmen; and a host of distinguished laymen who made a rich contribution to business, professional, public and church life, such as Sir Albert Spicer, Sir Murray Hyslop, Sir Arthur A. Haworth and Sir John McClure.

**20th Century.**—Among developments in the first half of the 20th century was a decline in church membership, which began in 1908 and continued with but little check in the mid-1920s up to the mid-1950s. This could be attributed mainly to conditions which brought like results to all denominations—the effect of two world wars, failure to adapt quickly enough to modern concepts of thought and conditions of life, and a serious loss of touch with all but the middle classes. The second was a tendency toward theological liberalism, marked by the publication of R. J. Campbell's *New Theology* (1907), a superficial but temporarily popular work. There was later a revived interest in the Christ-centred teachings of P. T. Forsyth, and valuable contributions were made to theology and biblical scholarship by A. E. Garvie, W. B. Selbie, J. Vernon Bartlett, George Buchanan Gray, Sydney Cave, John S. Whale, C. H. Dodd, Nathaniel Micklem and others.

The 20th century saw growth in the work and responsibility of the union for and on behalf of the churches. In 1904 a new constitution was framed and with modifications was in use until a new formulation was made in 1958. It put the union's business in the hands of a council of about 300 members in the main elected by the county unions. To it the Administration committee was responsible. These committees were steadily increased, notably by the addition of a young people's department in 1908, a committee for women's work in 1915 and a board of moderators in 1920. Nine moderators were appointed to be responsible for the churches and ministers in a number of county unions grouped into provinces.

In 1924 the Publications committee was converted into a private limited liability company called the Independent press. In 1922 the *Congregational Quarterly* was started with the historian Albert Peel as editor; it ceased publication in 1958. In 1950 the union took over the privately owned *Congregational Monthly*. Youth work was begun at denominational level in 1883 and reorganized in 1908. Pioneer work was done in the encouragement of graded Sunday schools, Christian education and later in the concept of the family church.

Perhaps the most important 20th-century development was the acceptance after World War II of responsibility for a guaranteed minimum stipend for ministers and the raising of the necessary means through the Home Churches fund. This led to the adoption of an over-all budget scheme for all the work of the union by the voluntary decision of the churches to provide funds.

In mid-century consideration was given to finding the means whereby the union and the London Missionary society might be integrated and thus organically express the unity of church and mission. The fact that the society served more than one Congregational union made the working out of such an arrangement difficult.

In 1945 the Presbyterian Church of England made proposals for union with the Congregational Union of England and Wales. A plan submitted to the churches was rejected by the Congregational assembly of 1949. Nevertheless in 1951 the assemblies of the two bodies met together and pledged themselves to close co-operation in terms of a covenant. As a result there was co-operation both at home and overseas and agreement was reached as to the recognition of each other's ministries and as to standards of faith. Though a small denomination, English Congregationalists have contributed largely to ecumenical work in the World Council of Churches and the International Missionary council, providing leaders out of proportion to their numbers.

#### SCOTLAND AND WALES

**Scotland.**—Scottish Congregationalism owes its beginnings to two laymen, the brothers Robert and James Haldane. In the period of political and social unrest at the close of the 18th century they sought to arouse the Church of Scotland to the need for missionary effort at home and abroad by making preaching journeys up and down the country and by establishing Sunday schools. Their failure forced the Haldanes and their associates to found a new denomination.

The real architect of Scottish Congregationalism, however, was Greville Ewing, minister of the Church of Scotland who left that church to assist the Haldanes and who became convinced of the scriptural authority for the Congregational polity. As minister of the mother church of the denomination in Glasgow (now Hillhead church) he was an unwearied itinerant in the cause of Congregationalism, a founder of its Ministerial Training college and of the Congregational Union of Scotland (1812). Alongside and succeeding him as leaders were such gifted men as Ralph Wardlaw of Glasgow and William Lindsay Alexander of Edinburgh.

In the first century of the union's history outstanding names are George Macdonald, David Livingstone, Robert Moffat, James Chalmers and P. T. Forsyth. But also the little denomination made a valuable witness in terms of its evangelical spirit, liberal outlook and encouragement of Christian democracy.

In 1896 the Congregationalists were united with the Evangelical union, formed in 1843 by three ministers of the United Secession Church (James Morison, A. C. Rutherford and John Guthrie), who had been expelled for preaching a gospel which conflicted with the prevailing Calvinism of the day. The Evangelical union expressed its faith in terms of the "three universalities": that God loves all men, that Christ died for all men and that the Holy Spirit strives with all men. In the 50 years of its separate existence it produced among others the theologian Andrew Martin Fairbairn and the Labour leader James Keir Hardie. The teachings and outlook of the Evangelical union were close enough to those of the Congregationalists to suggest amalgamation as early as 1867.

Congregationalism has never grown to any considerable size in

Scotland, having by 1960 a total of 150 churches and 34,500 members. It remains separate from, though in close fellowship with, the Congregational Union of England and Wales, and shares in support of the London Missionary society.

**Wales.**—While the English-speaking Congregationalists in Wales are included in the Congregational Union of England and Wales, those who originally spoke (and in many cases still speak) their native tongue are united as the Welsh Independents. Historically they trace themselves back to a revival which formed a church in 1639 in the village of Llanvaches in Monmouthshire. The flame of revival spread over the country and each century became the home of an Independent church.

In time the churches tended to group together for conference and preaching festivals. The first *gymanfa*, or festival, was held in 1778. Regular associations were also built up and attempts were made to form a union of all the churches. At last in 1871, when the Congregational Union of England and Wales was holding an autumnal assembly in Swansea, the Welsh delegates met separately, and with the approval of the English union formed the Union of Welsh Independents. There were then in Wales 897 churches, and gradually, according to their choice, they found their place in the new union or the English one. The two unions have maintained close contact and by constitution send official representatives to each other's assemblies and co-operate in certain matters. The independence of the local churches in Wales has always been jealously preserved, and the union has been given little authority and has not developed any considerable organization. There is only one full-time officer, much of the work of the committees and of the council (the executive body) being done on a voluntary basis.

A bookroom and publishing department was begun in 1907, and a weekly organ, *Y Tyst* ("The Witness"), is published. In 1911 a sustentation fund was started to help to maintain a minimum stipend for ministers.

The Welsh churches maintain two theological colleges, but during the first half of the 20th century one-third of all the students settled down in or moved into English churches, leaving a shortage of ministers in Wales itself. In 1960, 975 churches with 118,000 members were served by only 350 ministers. Many of the churches rely, therefore, on lay preachers. (R. F. G. C.)

#### UNITED STATES

**Beginnings.**—Congregational churches in the United States derive from two sources: the Separatists of Plymouth and the Puritans of the Massachusetts Bay colony. The former had taken refuge from persecution at Leiden in the Netherlands in 1608, but in 1620 a vanguard consisting of the younger members was sent to found a colony in the new world. They arrived on the "Mayflower" and settled at Plymouth. The greater portion of the Leiden congregation, including their pastor, John Robinson remained in the Netherlands.

The Puritans, who did not separate themselves from the Church of England but wished only to reform it, decided to leave England because of the persecutions under Archbishop Laud. They secured a charter for their colony from Charles I, and beginning in 1630 established settlements in considerable numbers in and around Boston. In organizing their churches they ordained their ministers congregationally, even when the latter had already been ordained episcopally. The introduction of the congregational polity into these Puritans belonged to the nonseparatist Congregational party in the English Church. Accordingly, both Plymouth and Massachusetts were congregational in polity. (See also PURITANISM.)

When presbyterianism became dominant in England, the religious leaders of New England were summoned to a synod at Cambridge, Mass., in 1648 to consider the implicit dangers of the event to their ecclesiastical structure. They decided to accept the Westminster Confession of Faith as their doctrinal statement. They adopted the thoroughly congregational *Platform of Church Discipline* (the so-called *Cambridge Platform*) for their polity. The Halfway covenant adopted in 1662 greatly affected the requirements for church membership, which originally depended

upon a profession of religious experience. Members had the right to present their children to be baptized and thus secured for them church membership. This system gave rise to an unforeseen difficulty: some of these children, upon growing up, did not profess religious conversion. It was decided that those who had acquired membership by virtue of baptism alone could not be regarded as in full communion. They retained all the privileges of church members except that they could not partake of the Lord's Supper and could not vote in church elections. But they could bring their children to baptism and pass to them the degree of membership the parents possessed.

Since a considerable group among the bay settlers consisted of university-trained men, interest in education was keen. This was evidenced in 1636 when the general court of Massachusetts voted funds for a college, to which the name of a minister, John Harvard, was given in 1639 (*see HARVARD UNIVERSITY*). Thus began the continuous program of organizing and sustaining colleges by the Congregational churches, an educated ministry being insisted upon from the earliest days.

**Great Awakening and After.**—The loss in religious fervour that occurred during the colonial period was a source of profound distress to the ministers of the Congregational churches. The general tendency of the time was to lay stress upon good works as the effective means of producing a religious experience, and preaching therefore was concerned largely with ethical idealism. It was not until about 1734 that a widespread and profound movement of religious revival began, which came to be known as the Great Awakening. Its origin was in the preaching of Jonathan Edwards (*q.v.*) of Northampton, Mass., a theologian and a preacher of unique power who ranks as perhaps the greatest intellectual leader produced in the Congregational churches. In 1740 George Whitefield came to America from England to help in the Awakening, news concerning which had produced a profound impression in the mother country. The movement then swept rapidly on. Many physical expressions of excitement accompanied the revival and created sharp divisions among the leaders. The good results of the Great Awakening are unquestioned, however. The moral standards of communities were lifted and religion became a vital factor in human experience such as it had not been before. A conservative estimate of the number added to the churches as a result of the revival is 25,000 out of a population of perhaps 300,000 in New England at that time.

The differences in opinion brought out by the Great Awakening, however, quickly deepened and soon the churches were torn by controversy. The old, stable Calvinism, which had been generally dominant, was sharply assailed by those who were not satisfied with its affirmations of the absolute sovereignty of God, the total depravity of man, the inability of the human will in the process of salvation and the doctrines of foreordination and election. Out of the discussions came at last the only distinctive system of divinity contributed by the United States to the history of doctrine. It was a form of modified Calvinism which is known as the New England theology, of which Jonathan Edwards and his followers were the principal exponents. Its basic tenet was emphasis upon the love of God in relation to men and the power of man in responding to the divine influence in the experiences of religion. But as was inevitable, the theological developments issuing from the Great Awakening swung to the left, and a strong Unitarian movement was incipient even when the Awakening was at its height. This did not come to full strength, however, until about 1800. Then the anti-Trinitarians became aggressive. In 1805 they secured the election of one of their number to the Hollis professorship of divinity at Harvard, thus entrenching themselves in the oldest college of Congregational heritage. Within ten years the Unitarian movement assumed such strength that it was able to carry a majority in many of the oldest and strongest of the New England Congregational churches, and, as a result of a favourable court decision, to maintain possession of the records and property of the organizations. In Boston, for example, out of 14 Congregational churches all but 2 became Unitarian, involving immense loss in members and money to the orthodox group, as they were currently known. In Massachusetts alone, 96 churches thus separated from

the Congregational organization. (*See UNITARIANISM.*)

The period from 1800 to 1850 was marked by close union in missionary work with the Presbyterians, who had little strength in New England but possessed larger resources in New York and Pennsylvania. In doctrine the two bodies were in practical agreement, both being Calvinists in their earlier history. In church government they were not sharply separated. When the westward emigration demanded organized agencies to follow the settlers with religious ministration, it was natural that the Congregationalists and Presbyterians should seek to work together. In 1801 they adopted the Plan of Union, and in 1808 the Accommodation Plan for Western New York, for the purpose of missionary expansion. When the Presbyterians split in 1837 over the theological consequences of the Plan of Union, the Old School Presbyterian Church repudiated the plan. The New School continued the co-operation with the Congregationalists until the latter repealed the agreement at the Albany convention of 1852.

**Theological Development.**—Despite the Unitarian defection from Congregationalism, the theological trends within the latter were toward liberalism. This showed itself, first of all, in the system of Nathaniel W. Taylor of the Yale divinity school, who taught a doctrine of free will that modified the older Calvinistic view. He asserted that even though God made the choice of evil possible, it was left to man's free will whether or not he would choose it. But even more important for this liberalizing tendency was the influence of Horace Bushnell (*q.v.*), the inspirer of the "New Theology." In his *Christian Nurture* (1847) he argued in opposition to the commonly accepted assumption that every child must pass through a religious crisis of conversion, that a child is to grow up as a Christian and never know himself as being otherwise. In his most radical book, *God in Christ* (1849), he sharply rejected the traditional "substitutionary" theory of atonement for one essentially consonant with the liberal interpretation of that doctrine.

These liberal views became widely disseminated among the Congregational churches and resulted in a theological cleavage between the Congregationalists and the more conservative-minded Presbyterians. When the Congregationalists met at the national council in Boston (1865), they adopted after much discussion the so-called Burial Hill confession (at Plymouth) in which they practically broke with their theological past and would no longer use the term "Calvinist" for themselves. The most popular of the exponents of this evangelical liberal point of view were Henry Ward Beecher and Washington Gladden (*qq.v.*). The so-called "Kansas City creed" of 1913 bore testimony to this liberal tendency.

**Organizational Developments.**—In 1810 the American Board of Commissioners for Foreign Missions was organized. While entirely Congregational in origin, it included in its membership, at first, representatives of the Presbyterian and Dutch Reformed churches; later both these bodies withdrew. After 1840 the board extended its work widely, and it came to play a part in missionary work in foreign lands, especially Turkey, quite out of proportion to the numbers and wealth of its supporting churches. During the same time the boards established for home missions and education set vigorously to work. The contribution of the American Missionary association to the education of Negroes was conspicuous, particularly after the close of the Civil War in 1865.

In 1871 was organized the national council, the functions and powers of which were carefully defined and delimited. It was not to possess autonomous powers but to serve the interests of the churches in national, international and other delegated tasks. Another step was taken at Kansas City in 1913. The national council was given larger functions in the work of the church, still safeguarding the autonomy of the individual congregation. A general secretary was chosen to represent the churches of the nation in their relations with small congregational groups, other denominations and internationally.

**United Church of Christ.**—The inherent ecumenicity of the Congregational churches was manifested in 1931, when the merger with the small body known as the Christian Church was consummated; the name of the fellowship was changed to the Congregational Christian Churches.

In 1938 union of the Congregational Christian Churches with the Evangelical and Reformed Church (for the history of which see REFORMED CHURCHES: *United States*) into a new denomination, to be known as the United Church of Christ, was proposed. The first draft of the Basis of Union was issued in March 1943 and the final version in Jan. 1947. Since the Evangelical and Reformed Church was a Presbyterian body, the principal difference concerned the polity of the new denomination. The two polities were combined into a new pattern, neither presbyterian nor congregational. The merger of the two bodies was to be effected first and the constitution worked out afterward. When the Basis of Union was submitted to the churches, associations and state conferences for voting, the norm of 75% set by the executive committee was not reached. Nevertheless, the general council of the Congregational Christian Churches held at Oberlin, O. (1948), declared the Basis of Union approved for itself (not for the churches).

This decision was repeated next year at Cleveland, O., after the period of voting was extended, although the 75% goal had not been reached. Negotiations were terminated by the Omaha council (1956), which, by a vote of 1,310 to 179 (with 11 abstentions), authorized "the holding of the General Synod of the United Church of Christ." This body, composed of delegates from the two denominations, met in June 1957 at Cleveland, O., and elected a constitutional committee. In July 1961 at Philadelphia a constitution was adopted, the union was consummated and the United Church of Christ established. (O. S. D.; M. SPI.)

#### INTERNATIONAL

Congregationalism as it is found in the United States, Australia, New Zealand, South Africa, British Guiana and Jamaica can be traced back directly to England—in many cases (including Canada and Newfoundland before the union of 1925) through the work of the Colonial (later the Commonwealth) Missionary society. Irish Congregationalism grew largely out of the work of the Irish Evangelical society. Congregationalism in Argentina and some of the Congregational churches in Brazil was sponsored by German Congregationalists in the United States.

Congregationalism, however, exists in other lands where it has grown spontaneously, though not always using the name. The Remonstrant Brotherhood in the Netherlands was formed in 1619, as a result of the teaching of Jacobus Arminius. The union of Evangelical Congregational and Christian churches of Brazil formed in 1942 traces its origin to an Englishman who began work there in 1855. The Free Church of Finland for political reasons could not be officially registered until 1922, but churches had then existed for more than 30 years. The Swedish Mission Covenant Church was formed in 1878 as an evangelical movement within the state Lutheran Church.

Representatives of Congregational churches from all parts of the world first met in an International Congregational council in London in 1891. They continued to meet alternately in England and the United States at approximately ten-year intervals for fellowship and the exchange of views and experiences. At the meeting held in the United States in 1949 the council was provided with a constitution, a permanent secretariat and an office in London. Later meetings were held every five years. The council has no delegated or other authority and its purpose is still generally conceived in terms of fellowship and service between its constituent members.

#### POLITY, WORSHIP AND DOCTRINE

**Polity.**—From the 16th century there have been differences of understanding as to the extent of the local autonomy and independence implied in the Congregationalist conception of the local church as the basic unit of Christian fellowship, worship and experience. It was necessary for the early churches to assert these rights against the authority claimed by the Episcopal Church in its orders, its creeds, its relation to the state, and against the authority of Presbyterian courts. The independence of the local congregations was also most suitable at a time when communications were difficult for a small scattered body. But time has

brought changes. Protestation is no longer a primary necessity. Co-operation among churches has become vital to their administration and survival. As a result, while the rights of the local congregation are still maintained, insistence on independence has largely disappeared. Councils and assemblies have been given considerable powers, if not considerable authority.

The local congregation, however, is still deemed the vital unit as a covenanted fellowship of committed Christians. Confession of faith and membership of the local church are undertaken together. In the church all members are deemed to be equal and to have equal responsibility exercised through the church meetings. These meetings are normally held once a month, less frequently in the United States. The ideal of participation by all, or even by most, church members, however, is rarely achieved.

The general care of the church is in the hands of the deacons—men and women elected by members to represent them in sharing with the minister in the spiritual care of the congregation, in the distribution of the elements at the Lord's Supper and in the general administration of the church and its organizations. Deacons are usually elected for an agreed number of years only.

Ordination to the Congregational ministry is by the call of God and the call of the local church. Whereas in earlier days that might be sufficient, now the denomination is involved in the standards of training (though the theological colleges are independent), in recognition of status and by representative participation in ordination itself. John Owen, in his *Discourses Concerning the Holy Spirit* (1693), maintained that while the ministry is necessary to render a church "completely organical," yet men may "become a church essentially before they have any pastor or teacher." This view was confirmed in 1929 by the assembly of the Congregational Union of England and Wales.

Nearly all Congregational churches are now involved together in associations or unions which cover district, county or state areas. In England and Wales these county unions are themselves represented in a council of 300. To this body all the committees or organizations of the union are appointed and to it they are responsible. The council in turn reports to an assembly, which however, is constituted by direct representation of the ministers and laity of every church. The assembly has no binding authority over local congregations. It does represent the collective mind of them all or of the majority, however, and its judgments or decisions generally, though not of necessity, are accepted. Increasingly the churches have accepted the value as well as the necessity of co-operation through an approved and controlled organization and have recognized that the Spirit of God may move in large as well as small associations.

**Worship.**—The central feature of Puritan worship was the sermon, the declaration and exposition of God's Word and the application of it to the hearts of the congregation. This has remained characteristic of Congregationalism. Its ministers are "of the Word and Sacraments"—in that order. The church service is in large measure designed to promote the sermon as its climax.

The central and focal point of a Congregational church is traditionally the pulpit. A 20th-century tendency to place the pulpit to one side of centre has been mainly for aesthetic reasons, though it does indicate some appreciation of the importance of features of the service other than the sermon.

The Puritans accepted only two sacraments, baptism and the Lord's Supper, as of dominical institution, and these are still the only two sacraments recognized. Baptism is normally infant baptism, though there are differences in the interpretation of the significance of the act. Believer's baptism is not uncommon. Baptism is not considered a prerequisite to acceptance into church membership but is normally deemed desirable. The Lord's Supper or Communion is observed in most Congregational churches once a month, or sometimes twice (in the morning on one Sunday and in the evening on another). It normally follows a preaching service, sometimes after a brief interval so that those who do not wish to partake may retire. The service usually is conducted by a minister assisted by deacons, but the church may approve of ministrations by a layman. Both the bread and wine are partaken

by all and are taken round to the congregation by the deacons. Nowadays the bread is almost always cut beforehand and the wine served in small glasses and not from a chalice. The wine, however, is drunk by all the congregation simultaneously. New church members are received at a Communion service and participation in the service is esteemed a mark and obligation of membership. An invitation is usually given, however, to "all who love the Lord Jesus Christ" to share in the service, which is thus open to all believers, whether members or not, and of any church. It once was customary to judge sincerity of faith by attendance at Communion and to remove from the membership roll those who without adequate explanation did not attend over a period of time; this is a dying custom.

The Puritans objected to set forms of prayer, or liturgies, as they did to set forms of preaching, or homilies. It was not until the end of the 19th century that experiments were made in the realm of ordered worship. Service books are now widely used, and various forms of liturgy, the use of set forms of prayer and unison reading of the Scriptures are often practised. The first official service book was *A Book of Congregational Worship* (1921); a later one is *A Book of Service and Prayers* (1959). Their use, however, is not compulsory and each church is free to devise its own forms. By the early 1960s there had been three Congregational hymnbooks, the one in general use being *Congregational Praise* (1951).

From no office of the church and from the performance of no service or sacrament are women excluded. The first ordination of a woman to a Congregational ministry in Great Britain occurred in 1917, and there are women ministers and deacons in all countries except Finland and those of South America.

**Doctrine.**—Congregationalists have always held that faith must be personal and direct. It is to be tested against the Holy Scriptures and no other formulation. There is, therefore, no creed or other statement of faith to which all do give, or any individual must give, assent. Church membership is entered into on a simple affirmation of personal acceptance of Jesus Christ as Lord and Saviour with such understanding of the implications of this as may be made known in the Scriptures, through the church and by experience. Nor does ordination to the ministry require assent to any creed.

This is not to say that the classic formulations of the faith are denied. They are extensively used as a help to belief and are sometimes repeated in church. Nor does this mean that Congregationalists have not formulated the faith which is generally believed among them. The Savoy Declaration of the Faith and Order . . . of 1658, in very large measure a duplicate of the Westminster Confession, set out the faith of Congregationalists of the period, not as prescribed form but as a statement of terms of communion. In America this formulation was preceded by the Cambridge Platform of 1648. Both were expressive of the Calvinistic views of the time.

Soon after the Congregational union was formed a formulation of 20 Principles of Religion was devised, and accepted in May 1833 as "the Declaration of the Congregational Body, with the distinct understanding, that it is not intended as a test or creed for subscription." In like manner U.S. Congregationalists expressed themselves in 1865, 1871 and 1883. In 1959 the Congregational Christian Churches of the United States as part of the United Church of Christ formulated a *Statement of Faith* which was adopted by the second general synod of that church as "a testimony and not a test." In the same year the Congregational Union of England and Wales set up a commission to devise a statement.

There cannot be said to be a Congregational theology. The teachings of John Calvin were strongly influential in earlier times. A reactionary movement toward Unitarianism in the United States at the beginning of the 19th century is described above. In Great Britain evangelical influences prevailed. Adventures in so-called liberalism in the early 20th century did not last. A middle-of-the-way evangelical orthodoxy would describe the present-day theological position of Congregationalism almost everywhere.

**CONGRESS, INTERNATIONAL:** see CONFERENCE, INTERNATIONAL.

**CONGRESS, UNITED STATES.** The historical roots of the United States congress are found in the parliamentary assemblies of the middle ages. Since that period there has developed in western society the concept of representation based on elections, with broad suffrage, and an expanded legislative function that includes the general control of the national government. The formal structure of congress, the legal powers embodied in a written constitution and the relationship between congress and the president, however, are reflections of the political ideas current in the 18th century. (See CONSTITUTION AND CONSTITUTIONAL LAW; LEGISLATURE; REPRESENTATION; SEPARATION OF POWERS.)

The basic theory under which congress operates is that all official governmental action must have a legal base. This means that congress must have continuing relations with the rest of the government and with society as a whole, to see to it that the existing law is adequate and to create new law. Congress has become a great political regulator for adjusting conflict in U.S. society and an agency for controlling the government departments (*q.v.*) through law, personnel standards, appropriations and criticism.

The United States constitution of 1789 created a congress with two houses, having specific but restricted legal authority and separated structurally from the executive department (under the president) and the judicial system (coming to a head in the supreme court). (See UNITED STATES [OF AMERICA]; *Administration and Social Conditions*; PRESIDENT; SUPREME COURT OF THE UNITED STATES, THE.) The two chambers have similar functions to perform, and they have adopted similar procedures for performing them. There are, however, certain differences, which will be developed below. The business of congress has increased manyfold since the 18th century, but congress has proved remarkably resilient in adapting itself to the changing demands of a changing society. The policy adopted by congress during its history is, of course, reflected in public law, and to this extent the political controversies in congress and the legal solutions proffered are an intrinsic part of United States history.

**Structure.**—*House of Representatives.*—The house of representatives has grown considerably since the first congress of 1789, which had 65 members. In the mid-1950s congress had 435 members, and that figure had remained constant since 1912. In addition to the members, there was one delegate each from Alaska and Hawaii and a resident commissioner from Puerto Rico. These territorial representatives had the privilege of speaking but not of voting. On admission of Alaska and Hawaii as states in 1959, two additional representatives were automatically provided for under the constitution, but at the next apportionment the membership returned to 435, the total authorized by statute law.

Membership of the house is reapportioned among the states every ten years, following the decennial census (U.S. constitution, art. i, sec. 2), under a plan known as the method of equal proportions. The procedure for allocation is prescribed in the Apportionment act of 1929, which, with amendments, is the governing statute. After receiving their quota of seats, the states determine the size and boundaries of the congressional districts. The national law does not require a state to create single-member districts, nor does it specify standards of compactness, uniformity or contiguity that must be followed. However, in 1964 the U.S. supreme court ruled that congressional districts within each state must be substantially equal in population. (See APPORTIONMENT, LEGISLATIVE.)

The biennial elections for the house of representatives are held in the various states on the Tuesday next after the first Monday in November, the elections being customarily organized and contested by the Democratic and Republican political parties (*qq.v.*). National laws regulating elections are found in the corrupt practice legislation (see CORRUPT PRACTICES), but for the most part the elections are regulated by the states.

Inasmuch as the political strength of candidates for the house of representatives may differ from that of the president, a situation may result where the president's party, although victorious in the presidential election, does not control congress, or loses control of congress in a midterm election. The disparity in relative electoral strength may have subsequent repercussions in the relationship between the president and congress.

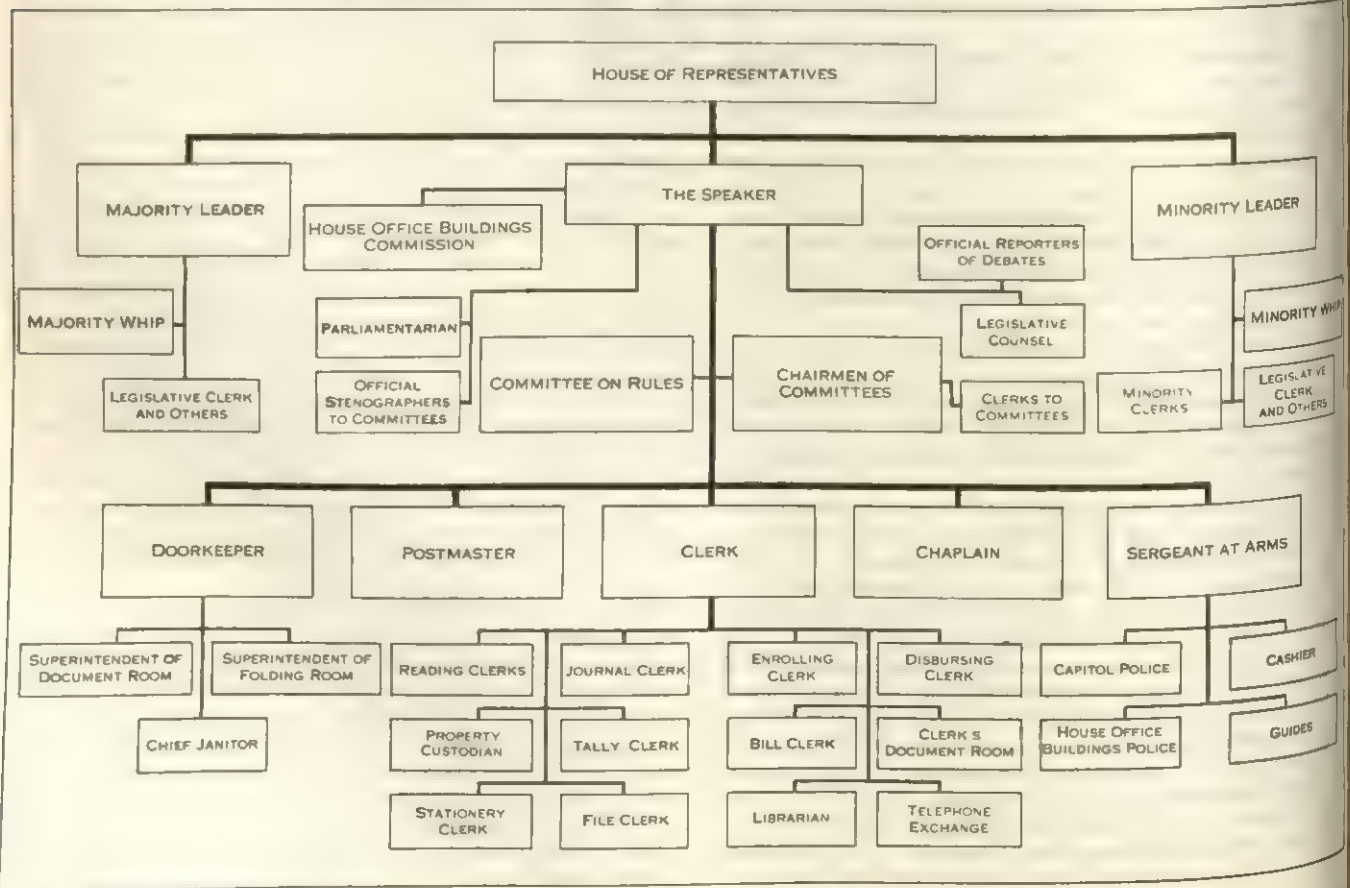

Disputed election contests are referred to a court or to a house committee; but the final decision on eligibility rests with the house of representatives, the constitution stating (i, 5) that "Each House shall be the Judge of the Elections, Returns and Qualifications of its own Members. . . ." The constitutional provisions for eligibility (i, 2) specify a minimum age of 25, United States citizenship for seven years and habitation in the state from which elected. Residence in a congressional district is not a constitutional requirement for eligibility, but candidates by custom reside in the district from which they are elected. The constitutional proviso (i, 6) that "no Person holding any Office under the United States, shall

be a Member of either House . . ." has the effect of preventing members of congress from heading the great governmental departments. This is one of the chief differences between parliamentary and congressional forms of government. If a member of congress accepts the offer, say, of the secretaryship of a department, he must resign his seat.

Once elected, a member has certain constitutional privileges (i, 6) to protect him against interference in carrying out his duties. He is privileged from arrest (in all cases except treason, felony and breach of the peace) during attendance at the sessions of congress or in going to and returning from the same. He cannot be questioned in a court of law "for any Speech or Debate" in either house, and he has certain prerogatives in the form of travel allowance, administrative and secretarial assistance, the use of the mailing frank, office space and, in the mid-1960s, an annual salary of \$30,000.

In its internal organization, the house of representatives retains certain ancient parliamentary offices, including the speaker of the house (see SPEAKER), the clerk of the house, the sergeant at arms and the doorkeeper. The historically ambivalent position of the speaker of the house is revealed in the several functions the speaker is required to perform, for he is at once the servant of the house in presiding over its deliberations, in the performance of which he should be impartial, and the leader of his own party. In presiding over the house of representatives, the speaker has the assistance of a skilled parliamentarian, who is a permanent employee of the house. The clerk of the house has general charge of the records, but his jurisdiction does not extend to the staff of the committees or of members' offices. There is no central recruiting agency for the employees of congress. Although some appointments are made on political grounds, there was an increase in the professional competence of the congressional staff after the enactment of the Legislative Reorganization act of 1946.

Political parties (see PARTY, POLITICAL) have developed within legislatures as a method for controlling the proceedings and mobilizing the necessary majorities. In establishing the authority and the structure of a partisan organization, the general problem may be stated to be that of providing sufficient control over the

general legislative process so that the house of representatives will be able to act affirmatively and at the same time to permit the members a measure of freedom in debate and in voting, consistent with the heterogeneous nature of United States parties and the legal equality of elected representatives. The party structure is now quite diffuse, earlier attempts to centralize control in the speaker of the house or in the rules committee or in a caucus having been found to be unsatisfactory. The recognized party leaders are (in addition to the speaker) the majority and minority floor leaders and the party whips; the chairmen of committees also have considerable partisan influence. For the purpose of showing the true lines of influence and authority, however, the organizational charts of congressional parties may be more impressive than accurate. It may not be too much of an exaggeration to say that, in addition to the recognized party leaders, a specific pattern of power develops for the consideration of every major policy issue.

The central unit of the party is the conference or caucus, the main function of which is to develop a skeleton party organization that will be responsible for carrying on the day-to-day functions of the house. The party leaders are selected; the committees are organized. In general, the parties attempt to secure party representation at all the points in the political process where significant decisions are made. They provide the initiative in selecting the agenda, in developing the debate and in mobilizing support for particular decisions, although they do not exercise exclusive authority in these areas. Party control over its own membership is not strong, and considerable latitude of action is permitted party members.

The committee system is an important adjunct to the work of the house of representatives. The committees play a significant part in selecting and preparing bills for the further consideration of the parent chamber, and their choice of bills may be influenced by the advice of the bureau of the budget, the interested governmental departments or the attitude of the president. It is customary, but not mandatory, for the committees to hold hearings on legislation at which interested parties are invited to give testimony. The committees also play a significant role in the control exercised by congress over the governmental agencies; departmental heads and other responsible officials frequently are called before committees to explain or justify policy.

The committees have considerable autonomy and are not required to report back to the house all bills referred to them. However, a committee may be discharged from considering a bill further; this process requires a petition carrying the signatures of a simple majority of the members. Legislation reported by a committee is placed on a calendar to await its turn, but if it is of sufficient importance it will be taken from the calendar and brought to the floor by means of a special rule reported by the rules committee. The function of this latter committee is to control the flow of legislation considered by the house and the amount of time consumed in debate. On the floor of the house, the committee members take the leadership in developing the debate on legislation previously considered in the committee.

There were in the early 1960s 20 committees in the house, which for the most part were organized around major policy areas. With the exception of some of the political leaders, all members are assigned to committees and are expected to participate fully. Each committee has a limited membership, and members belong to only one major committee. In view of the fact that membership is more desirable on some committees than on others, members do not necessarily get the assignment of their choice when they first enter the house of representatives. Members advance on the committee through the seniority system, the chairmanship normally going to the member of the majority party who has served longest on the committee. The Legislative Reorganization act of 1946 made provisions for each of the standing committees to acquire a professional staff that assists the committee in acquiring and processing information. The members may receive additional research assistance from the legislative reference service of the Library of Congress.

*Senate.*—The organization of the senate is in many ways similar

to that of the house of representatives, although its procedures are somewhat simpler. There is a less elaborate structure of political control, and, with its smaller membership, the senate is able to take action on many items by unanimous consent agreements.

With the admission of Alaska and Hawaii as states in 1959, there were 100 members of the senate, two from each of the states. The 17th amendment to the constitution (adopted in 1913) provides for the popular election of senators, whereas the constitution (i, 3) initially specified that senators were to be elected by state legislatures. In most states, vacancies may be filled by temporary appointments made by the governor.

The basic constitutional qualifications (i, 3) require a senator to have been a citizen of the United States for nine years, to be an inhabitant of the state for which chosen and to have attained the age of 30 years. The full term of office is six years, the terms of one-third of the senate membership ending every two years. The popular election of senators on a state-wide basis may require a considerable fiscal outlay (and this possibly in addition to the cost of conducting a primary campaign). Normally, the senate appoints a special committee to investigate and supervise the conduct of elections, and complaints of unfair tactics or violation of law may be referred to this committee. The compensation of senators is the same as that of representatives, but appropriations for clerical assistance are somewhat larger.

The senate is served by a staff that carries on functions similar to those of the staff of the house of representatives. In particular, the secretary of the senate has custody of the records and exercises general supervision of other employees, and the sergeant at arms has responsibility for security measures. The presiding officer is the vice-president of the United States, who is assisted by the president pro tempore of the senate, an honorific, elected office (i, 3). Each committee has its own staff, and so too do the individual senators. As in the house, the administration of senate personnel is highly decentralized.

Although partisanship and party organization are significant factors in senatorial behaviour, the party structure of the senate cannot readily be described by reference to an organizational chart. There are several political units, including for each party a conference, a policy committee, a steering committee and a committee on committees. However, the position taken by influential senators may be more significant than the action (if any) taken by a formal party structure. Each party elects a leader, generally a senator of considerable influence in his own right, who is in general charge of co-ordinating senate activities, making arrangements with his opposite number for the consideration of legislation and defending party interests on the floor. This somewhat loose party organization is responsible for organizing the senate, including the important function of naming senators to committees. Each party also selects a committee to give assistance in senatorial campaigns, such as fund raising. The congressional parties co-operate with the national political organization while retaining a degree of independence and freedom of action.

The senate in the early 1960s had 16 standing committees. These play a significant role in preparing legislation for consideration by the senate, and they also exercise control over governmental departments. The seniority rule is normally followed in the selection of a chairman, senators advancing in rank according to the length of their service on the committee. Because of the strategic nature of their position, the chairmen of the important senate committees often exert considerable influence over public policy.

*House and Senate.*—There are several aspects of the business of congress that the senate and house share in common and that require common action. One item of common concern is the date for convening and for adjourning congress. Congress begins its annual session in January (20th amendment), although the president may also convene either house on extraordinary occasions (ii, 3). The two houses customarily agree on a date for adjournment (i, 5), although the president has authority (ii, 3), which he has never used, to adjourn congress in the event the senate and house cannot agree on a date.

Another item of common concern is the joint session, which may occur when the president or other dignitary addresses both houses

or when the electoral votes for the president and vice-president are to be counted (ii, 1). A third item relates to certain subjects of concern to both houses. To meet this common need, committees having membership drawn from both houses may be created, examples being the joint conference committees (for adjusting disputes between different versions of legislation), the joint atomic energy committee and the joint committee on printing.

The common interests of the houses of congress also are served by several agencies that in a very particular sense are responsible to congress or to joint committees of congress. These agencies include the government printing office, the general accounting office, the Botanic garden and the Library of Congress. The independent commissions have an indeterminate status in the governmental structure; they are charged with carrying out the law of congress, but they are not directly responsible to the president.

**Process: House and Senate.**—The house and senate have similar functions to perform, and they have developed similar techniques and procedures for performing them. In considering legislation, the committees take up the proposed bills, selecting for special attention those for which there is some political support and perhaps holding hearings on them. The public hearing, with testimony given by government officials and representatives of special groups, has become an accepted adjunct of the congressional process. Many of the hearings before congressional committees are published by the government printing office and contain a considerable amount of information on public policy.

The house and senate follow slightly different procedures in reaching agreement on the legislation to be considered, but the process normally includes negotiation between the committees concerned and the leaders of the parties. Debate is controlled more strictly in the house than in the senate; a specific amount of time (several hours) is allotted in the house for considering the more important legislation, the time being controlled by committee leaders and reallocated to members who wish to participate in the debate. In considering legislation, the house may normally propose amendments, and on the demand of one-fifth of those present the yeas and nays are taken. A detailed account of the debate in congress is recorded in the *Congressional Record*, which has a daily edition as well as a permanent edition. Congress also publishes the *Congressional Daily Digest* and the *Congressional Directory*, and each house publishes its own *Journal* (i, 5), which contains a technical record of the proceedings.

Senate debate is considerably freer than house debate and less subject to rules and restrictions. In general, the practice is for the senate to debate a measure until everyone has expressed his view, although occasionally the senate will require all debate to terminate at a specified time. The unanimous consent agreement is one of the factors that enables the senate to complete action on minor business in a limited amount of time, leaving more time available for subjects of greater importance. The freedom of debate in the senate may be abused by a filibuster (*q.v.*), a device by which a member or members will talk on interminably in the hope that the item will not be voted on. However, the rules provide for a method of terminating debate by the application of cloture, which in the early 1960s required the support of two-thirds of the members who were present and voting.

For an act of congress to be valid, both the house and senate must approve an identical document. Differences may be adjusted if one or the other of the two chambers gives way, but in some cases a joint conference committee is appointed to negotiate an adjustment of difference.

In its annual sessions, congress has developed a routine for considering the various items of business that regularly arise. At the beginning of a session, the president delivers his state of the union address (ii, 3), which describes in broad terms the legislative program the president would like congress to consider. Later in January the president submits his annual budget message and the report on the economy prepared by the president's council of economic advisers. During the subsequent months, the president submits nominations and treaties for which the advice and consent of the senate are requested (ii, 2). Inasmuch as the committees require a period of time for preparing legislation before

it is considered on the floor, the legislative output of congress may be rather small in the early weeks of a session; the legislative calendars tend to be crowded in the closing weeks of a session. Legislation not enacted at the end of a session retains its status in the following session of the same two-year congress.

Meetings of the house and the senate are customarily open to the public (a card from a member's office is ordinarily required). Secret sessions (i, 5) are rare. The press gallery provides accommodations for representatives of various communications media. The sessions of congress, however, are not broadcast either over radio or television but exceptions are made for addresses to joint sessions.

**Position of the President and External Groups.**—For some purposes, the president may be considered to be a functioning part of the congressional process; congress also has constant and continuous relations with the various governmental agencies, either in making new policy or in determining the effectiveness of existing policy. If the electoral college fails to produce a majority of electoral votes for any one person, the house may select a president (each state delegation having one vote) and the senate may select a vice-president (12th amendment). The power of congress to provide for succession (ii, 1) of the president and vice-president was partly superseded in 1967 by the 25th amendment (see *PRESIDENT: United States: Vice-President*).

The president is expected to keep congress informed of the need for new legislation (ii, 3), and the various departments and agencies are required to send congress periodic reports of their activities. The president submits certain types of treaties and nominations for the approval of the senate (ii, 2). One of the most important of the legislative functions of the president, however, is that of signing or vetoing proposed legislation (i, 7). The president's veto may be overridden by two-thirds vote of each chamber, however. Nevertheless, the influence of the president's potential power may extend to the procedures of congress; the possibility that a bill may be vetoed gives the president some influence in determining what legislation congress will consider initially and what amendments will be acceptable. In addition to these legal and constitutional powers, the president has influence as leader of his party; he is in a position to mold party policy and to mobilize support for the policy both in congress and among the electorate.

The supreme court (iii, 1) has no direct relations with congress and does not give advisory opinions on the constitutionality of legislation. However, decisions on the constitutionality of legislation by the supreme court, and by other federal courts prescribe the constitutional orbit within which congress can act.

The representatives of interest groups are not part of the formal structure of congress, but they may play a significant role in testifying before congressional hearings and in mobilizing opinion on select issues. The Legislative Reorganization act of 1946 required the registration of lobbyists who attempt to influence the passage of legislation.

**Functions.—Legislation.**—The basic assumption underlying official governmental action is that all acts of authority must have a legal base. In actual fact, many of the activities of congress are not directly concerned with enacting law, but the ability of congress to enact law is often the sanction that makes its other action effective. The general legal theory under which congress operates is that legal authority is "delegated" to the president or departments or agencies, and that the latter, in turn, are legally responsible for their actions. In some areas of delegated legislation, such as in proposals for governmental reorganization, congress must indicate approval of specific plans before they go into effect. Congress may also retain the right to terminate legislation by joint action of both houses. The annual output of congressional legislation is found in the *United States Statutes at Large*, which are in turn codified in the *United States Code*. Rules and regulations (the terminology varies widely) based on legislation are found in the *Federal Register*, and this in turn is codified in the *Code of Federal Regulations*.

**Personnel.**—Congress exercises general legal control over the employment of government personnel, the basic policy being contained in the Classification act of 1923, as amended. Political

control may also be exercised, the chief vehicle being the senate's power to advise and consent to nominations. This control, in the broadest sense, enables the senate to set standards of policy and competence for appointments to high public office. The control may also act as a check on the personnel policy of the service departments.

The senate's authority over personnel may enable individual senators to exercise considerable influence in the selection of federal officers whose jurisdiction lies wholly within a state. Neither the senate nor the house, however, has any direct constitutional power to nominate or otherwise select executive or judicial personnel (although in the unusual event that the electoral college fails to select a president and a vice-president, the two houses, respectively, are expected to do so). Nor does congress customarily remove officials, although sustained criticism of personnel may lead to their resignation or removal by the president. Congress may have recourse, however, to the seldom-used power of impeachment. In such proceedings, the impeachment is made by the house of representatives (i, 2) and the case tried before the senate, a vote of two-thirds of the senators present being required for conviction (i, 3). The last impeachment trial was held in the senate in 1936; in all, there have been 12 impeachment trials and four convictions.

**Fiscal.**—The power to levy and collect taxes and to appropriate funds (i, 8) gives congress considerable authority in fiscal matters. The basic law outlining the broad procedures to be followed by the government in spending money and raising revenue is found in the Budget and Accounting act of 1921, and to this may be added certain congressional rules and procedures. The president has the initial responsibility for determining the proposed level of appropriations (a function performed with the assistance of the bureau of the budget), the estimates for the next fiscal year being submitted to congress in January. At the same time, the president submits his budget message. Congress does not enact a single budget bill but, rather, considers various departmental and other appropriation bills during the first six or seven months of each session. The house and senate appropriation committees hold hearings on the appropriation bills, taking advantage of the opportunity to review past policy of the departments and agencies. Additional fiscal control is exercised by the general accounting office, a congressional agency which audits governmental spending and settles accounts, reports of its action being submitted to appropriate congressional committees.

The president's budget message includes references to anticipated revenue and, possibly, recommendations for changing the tax laws. However, congress considers revenue measures independently; they are not an integral part of the process for appropriating monies. In either case, however, the house of representatives assumes the initiative. Bills for raising revenue must originate in the house of representatives, according to the constitution (i, 7), and by custom appropriation bills originate there also. Proposals for changes in the tax structure are made by the treasury department and are considered by the ways and means committee in the house and by the finance committee in the senate. The revenue committees are assisted in their work, such as estimating tax yield or the effect of tax change, by the professional staff of the joint committee on internal revenue taxation, in addition to their own staffs.

**Criticism and Investigations.**—The critical function of congress has developed from its concern with the effectiveness of existing legislation and the necessity for new legislation. The expression of criticism takes several forms, ranging from debate to special inquiry. The custom has developed of inviting department heads and subordinates to testify before committees on matters of controversial public policy. The interrogation of department heads never takes place on the floor of the house or senate, although very occasionally the president or a departmental secretary will formally address one or both houses.

The most formal type of interrogation occurs when a committee or subcommittee conducts a special investigation, the object of the inquiry being set forth in a resolution passed by the parent body. In preparation for such an investigation, the general pro-

cedure is to grant a committee special authority to investigate a particular subject, special power being authorized to compel the attendance of witnesses and the production of papers. The exercise of this authority, in turn, has led to considerable adjudication in which the courts have been asked to determine the extent of congress's power to investigate. The broad powers of congress in this field have been upheld by the courts, although some cases have emphasized the importance of meticulous procedures. In the case of *McGrain v. Dougherty* (273 U.S. 135 [1926]), the supreme court said that "the power of inquiry—with process to enforce it—is an essential and appropriate auxiliary to the legislative function." This general principle was not changed in subsequent judicial rulings.

One of the most contentious phases of investigations is, and has been, the refusal of witnesses to testify. In its early history, congress itself punished contumacious witnesses, but subsequently it empowered the federal courts to try cases of contempt. The most effective claim for refusing to testify has been the protection offered by the 5th amendment to the U.S. constitution, which provides, among other things, that "no person . . . shall be compelled in any criminal case to be a witness against himself." However, special legislation also provides that, under certain judicial conditions, committees may compel testimony by guaranteeing that the witness will be immune from prosecution arising from his testimony. In the important case of *Watkins v. United States* (354 U.S. 178 [1957]), the court held that the 1st amendment protects a witness from identifying former Communist associates. Congress, the court said, has no "general power to expose where the predominant result can only be an invasion of the private rights of individuals."

## CONGRESS OF INDUSTRIAL ORGANIZATIONS:

see AMERICAN FEDERATION OF LABOR—CONGRESS OF INDUSTRIAL ORGANIZATIONS.

**CONGREVE, RICHARD** (1818-1899), English philosopher, a Comtian positivist, was born at Leamington on Sept. 4, 1818, and educated at Rugby and at Wadham college, Oxford, where he obtained a fellowship. Inspired by a meeting with Auguste Comte (q.v.; see also POSITIVISM) he became a convinced positivist, resigned his Wadham fellowship (1855) and founded the positivist Church of Humanity in Chapel street, Holborn. In 1878, however, he caused a schism among positivists by repudiating the authority of Comte's successor, Pierre Lafitte. Afterward Congreve concerned himself especially with the ceremonial elaboration of the positivist religion. He died in Hampstead on July 5, 1899.

Congreve's positivist writings include *The New Religion in Its Attitude Towards the Old* (1859), *Essays, Political, Social and Religious*, 3 vol. (1874-1900), *Human Catholicism* (1876-77) and translations from Comte. He also published some historical works (collected ed., *Historical Lectures*, 1900), a translation of Aristotle's *Politics* (1855) and occasional notes on current affairs, such as pamphlets urging the British to evacuate Gibraltar and India.

**CONGREVE, WILLIAM** (1670-1729), English dramatist, the most brilliant of the writers of Restoration comedy, was born at Bardsey, near Leeds, on Jan. 24, 1670. In 1674 his father was granted a commission in the army to join the garrison at Youghal, in Ireland, being moved later to Carrickfergus, whence, in 1681, Congreve was sent to school at Kilkenny, the Eton of Ireland. In April 1686 he entered Trinity college, Dublin (of which he became M.A. in 1696), under the famous St. George Ashe, who also tutored his elder schoolfellow, Jonathan Swift. It was prob-

ably at the revolution of 1688 that the family moved to the Congreve home at Stretton in Staffordshire, Congreve's father being made estate agent to the earl of Cork in 1690. In 1691 he was entered as a law student at the Middle Temple. Never a serious reader in law, in 1692 he published a light but delightfully skilful near-parody of fashionable romance, possibly drafted when he was 17, *Incognita, or Love and Duty Reconcil'd*, which he issued over the name of Cleophil. He quickly became known among men of letters, had some verses printed in Charles Gildon's 1692 *Miscellany*, and was favoured by Dryden, who in that year published his translation of the satires of Juvenal and Persius (dated 1693), in which Congreve collaborated, contributing also the complimentary lines "To Mr. Dryden."

It was in March 1693 that he leaped into fame with the production at Drury Lane of *The Old Bachelor*, written, he said, in 1690, to amuse himself during convalescence. Warmly heralded by the ever-generous Dryden, who declared that he had never read so brilliant a first play, though it needed to be given "the fashionable Cutt of the Town," it was an enormous success, running for the then unprecedented length of a fortnight. But his next play, *The Double Dealer*, played in November or December at the Theatre Royal, Drury Lane, though far better, and introduced when printed by some over-panegyrical lines from Dryden, did not meet with the same applause. *Love for Love*, however, his best acting play, almost repeated the success of his first. Acted in April 1695, it was the first performance staged for the new theatre in Lincoln's Inn Fields, which was opened after protracted crises in the old Theatre Royal, complicated by quarrels among the actors, which had induced the lord chamberlain to issue a new licence to run concurrently with that of the old patentees at Drury Lane. Congreve became one of the managers of the new theatre, promising to provide a new play every year.

In 1695 he began to write his more public occasional verse, such as his pastoral on the death of Queen Mary, and his ode "To the King, on the taking of Namur"; and John Dennis, then a young, unsoured critic, collecting his *Letters upon Several Occasions* (published 1696), extracted from Congreve his *Letter Concerning Humour in Comedy*. By this time Congreve's position among men of letters was so well established that he was considered worthy of one of those posts by which in those happy days men of power in government rewarded literary merit: he was made one of the five commissioners for licensing hackney coaches, though at a reduced salary of £100 per annum.

Though Congreve signally failed to carry out his promise of writing a play a year for Lincoln's Inn, he showed his good intentions by giving into their hands *The Mourning Bride*. Improbable as it may seem to modern readers, this tragedy, produced early in 1697, enormously swelled his reputation and was his most popular play. No further dramatic work appeared for three years. In April 1698 appeared Jeremy Collier's famous attack, *A Short View of the Immorality and Profaneness of the English Stage . . .*, a vigorous document composed partly of fantastic argument and absurd statement, and on the other hand of shrewd, common-sense observations which had a great deal of validity. Congreve was not the sort of man to enter into this kind of literary fisticuffs, but, under pressure and on his behalf alone, he replied with his *Amendments of Mr. Collier's False and Imperfect Citations* (July) which, though not so poor as is usually taken for granted, was as little effective as most of the other answers. Then in March 1700, Lincoln's Inn Fields produced Congreve's masterpiece, *The Way of the World*, with a brilliant cast, which, though it is now his only frequently revived piece, was a failure with the audience. This was Congreve's last attempt to write a play, though he did not entirely desert the theatre. He wrote libretti for *The Judgment of Paris*, performed in 1701, and for *Semele*, printed in 1710. In 1704 he collaborated with William Walsh and Sir John Vanbrugh in translating Molière's *Monsieur de Pourceaugnac* for Lincoln's Inn Fields as *Squire Trelooby* (not the version now printed, which is by Ozell), and in 1705 associated himself for a short time with Vanbrugh in the Queen's theatre, or Italian Opera house, writing an epilogue to its first production.

The rest of his life he passed quietly enough, being in easy cir-

cumstances, thanks to his private income, the royalties on his plays and his not very exacting posts in the civil service, though they were by no means sinecures. In 1705 he was made a commissioner for wines, a post that he retained by virtue of Swift's good offices at the change of government in 1710 but which he relinquished in 1714 when he became an undersearcher in the customs; this latter post was bettered at the end of 1714 with the addition of the secretaryship of the island of Jamaica. He wrote a considerable number of poems, some of the light social variety, some soundly scholarly translations from Homer, Juvenal, Ovid and Horace, and some Pindaric odes. In these odes he indited a timely *Discourse on the Pindarique Ode* (1706), which brought some order into the wildly unrestrained form which poets since Abraham Cowley, forgetting Ben Jonson's example and ignoring the remarks of Edward Phillips (Milton's nephew), had indiscriminately proliferated. His friendships were numerous, warm and constant, as much with insignificant people, such as his early companions in Ireland, as with the literary figures of his time. His quarrels are attributed to him, except for a very brief one with Jacob Tonson the publisher. Swift, whose friendship with him had begun in early days in Ireland, was unvarying in his affection for Gay he was the "unreproachful man"; Pope dedicated his *Essay* to him; and Steele his edition of Addison's *The Drummer*. As to his relations with the other sex, his *tendre* for Mrs. Bracegirdle—who acted most of his female leads—is well known; they were always close friends, but whether the intimacy was of a deeper nature is undetermined. In his later years he was devotedly attached to the second duchess of Marlborough, and it is almost certain that he was the father of her second daughter Lady Mary Godolphin, later duchess of Leeds. This would account for the large legacy, of almost all his fortune, to the duchess of Marlborough. He died in London on Jan. 19, 1729.

**Character and Literary Achievement.**—Congreve's character was praised in Giles Jacob's *Poetical Register* (1719), where he is described as being "so far from being puff'd up with Vanity . . . that he abounds with Humility and good Nature. He does not shew so much the Poet as the Gentleman." The last phrase will serve as a gloss on the notorious meeting with Voltaire, who in 1726 had come tuffhunting in England, and wished to extract what he could from the great English writer of comedy. Congreve, fading, fatigued, attacked by gout and half-blind "retired without regret, . . . In easy contemplation soothing time" ("Letter to Lord Cobham"), did not feel equal to discussing the minutiae of comic writing, or a play he had written some 30 years earlier. He told Voltaire that he would be delighted to talk on general subjects, "on the footing of a gentleman" as he phrased it, but not on subjects of which he would be expected to display expert critical knowledge and affect the pundit.

Congreve is the outstanding writer of the English comedy of manners, markedly different in many respects from others of the sparkling period of the drama. This comedy was a development, shaped by the political and social conditions of the time, unlike late Stuart comedy, and really owed little to the French. Taken as its main theme the manners and behaviour of the class to which it was addressed, that is, the antipuritanical theatre audience drawn largely from the court, it dealt with fops, fanatics, fools, exacting amateur scientists, imitators of French customs, concealed sexual fantasies of all kinds; but its main theme was above all the sexual life led by a large number of courtiers, not to mention Charles II. with their philosophy of freedom and experimentation. The dramatists dealt with it variously: Sir George Etherege a life-flippantly, finding the whole scene in the main vastly enjoyable; William Wycherley with a deep, savagely satirical revulsion against the whole scene; Colley Cibber with a clumsy sentimentalism, which expressed rather the indignant rebellion of the middle-class citizenry than any thought-out attitude. Yet it was all, without exception, critical comedy, aiming to "cure excess" by bringing "the sword of common sense" to bear upon the extravagant assumptions of the age. Where Congreve rises almost immeasurably above them is in both the delicacy of his feeling and the perfection of his phrasing.

The latter is strikingly exhibited in the opening speeches of

*Old Bachelor*, a play which no doubt appealed to the audiences because it handled with a new brilliance themes they were familiar with. If some of the repartee seems cheap and schoolboyish, that was the manner of the time. As Congreve progressed his speeches became more modulated, more musical, but always sure in their cadence. "Every sentence is replete with sense and satire," Hazlitt wrote, "conveyed in the most polished and pointed terms." As Meredith stated, "He is at once precise and voluble . . . in this he is a classic, and is worthy of treading a measure with Molière." He did not, however, achieve perfection until his last play, for he was not quite certain of himself, confusing a realistic presentation with an atmosphere of fantasy. It was perhaps this confusion which puzzled the audiences at his second play, *The Double Dealer*, which is in part clearly satirical and in part more purely comic. But he was not naturally satirical, being loath to portray "fools so gross, that . . . they should rather disturb than divert the well-natured and reflecting part of an audience"; and Pope was to ask, "Tell me if Congreve's fools are fools indeed." His real contribution begins to be felt in *Love for Love*, where the lovers express that fear of disillusion that comes with too easy fruition. What he had to say comes out clearly in *The Way of the World*, a play marred by the artificial contrivances of the plot. Here he is doing more than hold up to ridicule the assumptions that governed the society of his time. He could not regard love merely as the gratification of lust or as a battle of the sexes, a matter of wit rather than of feeling. He was averse from "rationalizing" love. The famous "bargaining scene" between Mirabel and Millamant is a plea for maintaining the valuable elements in sexual affection, a defense against the cynicism that pervaded, if not society, at least the stage. There is something tragic, too, about Lady Wishfort in her desperate attempt to preserve her youth. Congreve goes deeper than any of his contemporaries, has more feeling for the individual, and is far subtler. The equal of Molière? No. But the nearest English approach to him.

*The Mourning Bride* deserves better than the contempt which has been bestowed upon it for so long. Though the plot is outrageously fantastic, the poetic force behind it is not to be despised, and it has contributed two famous quotations to the common stock. Nor is Congreve's poetry negligible, though very minor. His love-pieces reveal that delicacy and respect for personality that characterize his two last comedies. His final poem, posthumously published, the "Letter to Lord Cobham" (his old friend Sir Richard Temple), is a fine example of the "retirement" poetry sporadic at that period, and his libretti are beautifully phrased for setting to music. Congreve was not a great poet, but he was a sensitive craftsman and nothing came from his hand that was not thoughtfully conceived and expertly contrived.

**BIBLIOGRAPHY.**—*Works: The Works of William Congreve*, 3 vol., appeared in 1710. Leigh Hunt's ed. *The Dramatic Works of Wycherley, Congreve . . .* (1849) contains a biographical and critical notice, as does *The Comedies of William Congreve*, 2 vol., ed. by G. S. Street (1895). *Semele* was ed. by D. D. Arundell (1925), and *Incognita* by H. F. B. Brett-Smith (1922) and again by the Folio society (1951). *The Complete Works of William Congreve*, 4 vol., ed. by M. Summers (1923), contains the letters and *Squire Trelooby*, and stage histories of the plays. The "World's Classics" edition, 2 vol. (1925, 1929) ed. by B. Dobrée, omits *Squire Trelooby*. Both have biographical and critical introductions. Some unedited fragments appear in *A Sheaf of Poetical Scraps* ed. by D. Protopoulos (1925), and some letters in Hodges (see below).

**Biography.** Early lives are valueless. Edmund Gosse's *Life of William Congreve* (1888; rev. ed. 1924) was the first full biography, succeeded by D. Protopoulos, *Un Classique Moderne, William Congreve* (1924). By far the fullest and most accurate is that by John C. Hodges, *William Congreve, the Man* (1941). A brief account is given by Kathleen M. Lynch in *A Congreve Gallery* (1951), which contains an admirable bibliography. Contemporary references are to be found in the letters of Swift, Pope and Gay, and in Swift's *Journal to Stella*. **Criticism:** Besides that included in the introductions mentioned above, detailed criticism is to be found in John Palmer, *The Comedy of Manners* (1913); B. Dobrée, *Restoration Comedy* (1924); Henry Ten Eyck Perry, *The Comic Spirit in Restoration Drama* (1925); Norman N. Holland, *The First Modern Comedies* (1959). (B. Do.)

**CONGRUENCE**, in mathematics, is a term employed in several senses, each connoting harmonious relation, agreement or correspondence.

Two geometric figures are said to be congruent, or to be in the

relation of congruence, if it is possible to superpose one of them on the other so that they shall coincide throughout. Thus two triangles are congruent if two sides and their included angle in the one are equal to two sides and their included angle in the other. This idea of congruence seems to be founded on that of a "rigid body," which may be moved from place to place without change in the internal relations of its parts. But it must rest on a previous concept of metrical relations among the parts of the body, since otherwise there would be no basis on which to determine whether the body had changed in shape and size.

The position of a (straight) line (of infinite extent) in space may be specified by assigning four suitably chosen co-ordinates. A congruence of lines in space is the set of lines obtained when the four co-ordinates of each line satisfy two given conditions. For example, all the lines cutting each of two given curves form a congruence. The co-ordinates of a line in a congruence may be expressed as functions of two independent parameters; from this it follows that the theory of congruences is analogous to that of surfaces in space of three dimensions. An important problem for a given congruence is that of determining the simplest surface into which it may be transformed.

Two integers  $a$  and  $b$  are said to be congruent modulo  $m$  if their difference  $a-b$  is divisible by the integer  $m$ . It is then said that  $a$  is congruent to  $b$  modulo  $m$ , and this statement is written in the symbolic form  $a \equiv b \pmod{m}$ . Such a relation is called a congruence. Congruences, particularly those involving a variable  $x$ , such as  $xp \equiv x \pmod{p}$ ,  $p$  being a prime number, have many properties analogous to those of algebraic equations. They are of great importance in the theory of numbers.

See DIFFERENTIAL GEOMETRY; DIOPHANTINE EQUATIONS; NUMBERS, THEORY OF; *Congruences in One Unknown*; TRIANGLE: Congruence.

**CONIBO**, a warlike tribe of Panoan (q.v.) linguistic stock living in Peru on the Ucayali river in the vicinity of the Pachitea. They live in palm houses sheltering about ten persons each, grouped in small communities of three or four houses. They welcomed Jesuit and Franciscan missions in the late 17th century in order to obtain iron, but soon revolted.

War raids were conducted in order to obtain slaves from weaker neighbours. Formerly, dugout canoes were made up to 60 ft. in length. They manufactured fine pottery decorated in red, black and cream designs, wove cotton textiles, and practised tropical agriculture. For hunting, spear throwers, long palmwood bows and arrows and, later, the blowgun were used. Shamans were influential; they diagnosed and cured sickness and foretold the future. Elaborate puberty ceremonies for girls were practised. Formerly, urn burial was practised at death; later, cremation. When parents became old, they were killed and eaten. During the 1960s the estimated population of the Conibo was 3,000.

(M. W. St.)

**CONIC SECTION.** If a right circular cone is cut by a plane, the boundary curve of the intersection is said to be a conic section or, more briefly, a conic. According to the angle of intersection the conic is a parabola, ellipse, circle or hyperbola. The ellipse, like the circle, is a closed curve (see fig. 1). In the case of the parabola the cutting plane is parallel to an element (see CONE); the parabola is therefore an open curve (see fig. 2). The hyperbola consists of two open branches lying on the two symmetrical sheets (nappes) of the cone (see fig. 3).

**Greek Mathematicians; the Geometrical Viewpoint.**—The description of conics given above is due to Menaechmus of Greece (c. 350 B.C.), the first man known to have considered the conic from a geometrical point of view. Menaechmus was a pupil of both Plato and Eudoxus of Cnidus. None of his writings are extant, but information about him is contained in works of other authors.

FIG. 1.—ELLIPSE (UPPER CURVE) AND CIRCLE (LOWER CURVE)

FIG. 2.—PARABOLA

FIG. 3.—HYPERBOLA

Menaechmus was led to the study of conics by his efforts to solve the problem of constructing a cube twice as large, by volume, as a given cube (the so-called Delian problem).

Euclid wrote four books on conic sections, but his work is completely lost. Archimedes succeeded in finding the area of the ellipse and of a sector of the parabola by a method closely akin to that of integral calculus, although calculus was not developed until the 17th century.

The pinnacle of Greek geometry, and perhaps of Greek mathematics in general, was reached in the eight books on conic sections by Apollonius of Perga (*q.v.*). Only the first seven have survived. Apollonius was the first to show that all conics are sections of any circular cone, right or oblique. But in studying these curves Apollonius treats them as plane curves, without regard to their spatial origin. The terms ellipse, hyperbola and parabola were introduced by Apollonius. His books contain the elementary theory of conics in a complete form.

Succeeding generations of Greek mathematicians added but little to the admirable treatise of the "Great Geometer," as Apollonius was called. However, an important contribution by Pappus of Alexandria should be mentioned. Pappus, who flourished about A.D. 320, showed that the ratio of the distances of any point on any conic from a fixed point (the focus) and a fixed line (the directrix) is constant. (This statement gives the analytical definition of a conic section.) The constant ratio is called the eccentricity and is denoted by  $e$ . The conic is an ellipse if  $e < 1$ , a parabola if  $e = 1$  and a hyperbola if  $e > 1$ ; for a circle,  $e = 0$ .

With the close of the Greek period interest in conic sections waned, and these curves were largely neglected until the first half of the 17th century.

**Desargues; Conics as Projections of a Circle.**—Like the "ancients," with whose works he was thoroughly familiar, Gérard Desargues approached the study of the conic by considering it as a section of a circular cone cut by a plane. But Desargues soon parted company with his predecessors and mentors by adopting a different point of view. He observed that the conic may be considered as an image, in the plane of section, of the basic circle of the cone or, in other words, that the conic is the projection of that circle from the vertex of the cone upon a second plane. Furthermore, if that conic in turn is projected the same way from another point upon a third plane, the image obtained is a conic. This concept of projection led Desargues to attribute to two parallel lines a common point "at infinity," and, further, to conclude that the points at infinity of all the lines in the plane lie on a straight line, "the line at infinity," thus adjoining the infinite domain to geometry.

Any figure in the plane of the initial circle gives rise, by the same operation of projection, to a corresponding figure in the new plane. Desargues noticed that some of the properties of the circle, and of the other figures in its plane, are reproduced in the new plane in a distorted way, while other properties are preserved and are identifiable in the new figure. He was thus the first geometer to draw a sharp distinction between the two kinds of geometrical properties, the "metrical" and the "projective."

Given a line  $m$  and a point  $O$  on it, the points of  $m$  may be paired off in such a way that the product of the distances, from  $O$ , of any pair of points is equal to a given constant, say  $K$ . Desargues said that the points of  $m$  paired off in this fashion are "in involution," and that the point  $O$  is the centre of the involution (*q.v.*). He showed that if a quadrilateral PQRS (see fig. 4) is inscribed in a conic ( $C$ ); and if  $m$  does not pass through any of the points  $P, Q, R, S$  the line  $m$  meets the two pairs of sides (PQ, RS), (PS, QR) and the conic ( $C$ ) in three pairs of points which are in involution. Moreover, any other conic passing through the points

FIG. 4.—QUADRILATERAL INSCRIBED IN CONIC SECTION

$P, Q, R, S$  will meet the line  $m$  in a pair of points belonging to the involution (Desargues's theorem on pencils of conics).

If a triangle  $ABC$  lying in a plane ( $P$ ) is projected from a point  $S'$ , not in ( $P$ ), upon a plane ( $P'$ ) into the triangle  $A'B'C'$  (see fig. 5), the sides of the latter triangle meet the line of intersection  $m$  of the planes ( $P$ ), ( $P'$ ) in the same three points as do the corresponding sides of  $ABC$ . The proposition remains valid for two coplanar triangles: If the three lines joining the corresponding vertices of the two triangles are concurrent, the three points of intersection of the corresponding sides are collinear.

FIG. 5.—PROJECTION OF TRIANGLE ABC

Desargues was the first mathematician of modern times who showed marked originality in the treatment of conic sections, and was easily the greatest geometer of the 17th century.

**Descartes; the Analytical Viewpoint.**—The Greeks never referred to their geometry as being "pure" or "synthetic," for they knew of no other kind. Desargues in this respect adhered to the ways of the Greeks, although he was familiar with the work of his friend René Descartes. The latter was the first to point out, in his *Geometry* (1637), that the resources of algebra (*q.v.*) may be brought to bear upon the study of geometrical figures in general, and conic sections in particular. He is thus the father of Cartesian or analytic geometry (*q.v.*).

From the analytical point of view a conic section is the graph of an equation of the second degree in two variables,  $x$  and  $y$ , namely,

$$ax^2 + by^2 + 2cxy + dx + ey + f = 0,$$

where the coefficients are constants for a given conic and vary from one conic to another. This algebraic definition of a conic reveals at once the interesting fact that a conic is, in general, determined if five points of that conic are given. Indeed, if the co-ordinates of the five points are substituted, in turn, into this equation, five linear homogeneous equations in the coefficients are obtained. When solved simultaneously they yield, in general, the values of the coefficients in the above equation of a conic, and the conic may be graphed.

By a proper choice of co-ordinate axes the general equation of a conic may be reduced to one of the three standard forms

$$x^2/a^2 + y^2/b^2 = 1 \quad (1)$$

$$x^2/a^2 - y^2/b^2 = 1 \quad (2)$$

$$y^2 = 2px \quad (3)$$

which represent an ellipse, hyperbola and parabola, respectively. Equation (1) shows immediately that if a point of the ellipse has for its co-ordinates  $(x_0, y_0)$ , then the co-ordinates  $(-x_0, -y_0)$  also satisfy equation (1); this shows that the origin is a centre of symmetry of the curve. If one of the two points  $(x_0, y_0)$ ,  $(-x_0, -y_0)$  lies on the ellipse, the other does also, and the  $x$ -axis is thus an axis of symmetry of the curve (that is, the lower part of the curve is the reflection of the upper part, the  $x$ -axis acting as a mirror). Similar reasoning holds true for the  $y$ -axis. The segments which (1) determines on these two axes are respectively equal to  $2a$  and  $2b$ . These segments are said to be the major and minor axes of the ellipse. The ends of the major axis of (1) are the vertices of the ellipse.

Analogous results for the hyperbola are readily obtained from the equation (2). The parabola (3) has no centre of symmetry. The  $x$ -axis is an axis of symmetry. The origin is the vertex of the curve and the  $y$ -axis is tangent to the curve at the vertex. Equation (3) is the focus of a point whose distances from a fixed point (focus) and a fixed line (directrix) are equal.

The above discussion illustrates the new point of view which Descartes revealed to his contemporaries through his analytical methods in geometry.

**Projective Description of Conics.**—The third phase in the study of conic sections came with the development of projective geometry. If  $A, A'$  are two fixed points of a circle and  $M$  a variable point of that circle, the lines  $AM, A'M$  describe two pencils of lines

(A), (A') such that to every line of (A) there corresponds a definite line of (A'), and vice versa (see fig. 6). Moreover, if  $a, b, c, d$  are any four lines of (A) and  $a', b', c', d'$  the corresponding lines of (A'), the angles  $a'c', c'b', c'd', d'b'$  are equal to the angles  $ac, cb, ad, db$ , respectively, and thus their sines are equal. Therefore, the anharmonic ratios (see PROJECTIVE GEOMETRY) of those two tetrads of lines are equal, and thus the two pencils of lines (A), (A') are projective. Now if this circle is projected from a point S not in its plane and the projecting figure (which is a circular cone) is cut by another plane not passing through S, the circle will be projected into a conic and the two pencils of lines into two other pencils of lines projective to each other. Corresponding lines of those pencils will intersect on the conic. Thus the following important proposition is obtained: If two pencils of rays in the same plane are projective, their corresponding rays intersect in points lying on a conic which passes through the centres of the two pencils.

FIG. 6.—PROJECTIVE PENCILS OF LINES

There is thus a projective mode of generation of a conic section.

**CONIFERS (CONIFERALES).** This is a large group of usually evergreen, cone-bearing trees, of which the pine, Douglas fir, hemlock, spruce, redwood and cedar are familiar examples. Coniferous forests are the major plant resource of North America, because of their value in furnishing building materials, pulpwood and many other lesser-known products. In addition to their economic importance, they are of great interest to the evolutionary biologist because they combine a nearly unbroken record of the past with a fascinating variety of types in existence today.

The order Coniferales is the largest order of the gymnosperms and includes about 48 genera with approximately 520 species which are found in all parts of the world. Usually they are trees of good size with profusely branched stems, in contrast to many other gymnosperms. There is a lateral growth zone or cambium which gives rise to a large amount of wood surrounded by a thin cortex and enclosing only a small amount of pith. Conifers also lack the ciliated swimming male gametes found in the cycads and ginkgo, having instead essentially naked male nuclei. The leaves of conifers also differ from those of other gymnosperms for they are never compound, but usually small and simple, needlelike leaves that persist for about three to ten years. In the larch (*Larix*) and the golden larch (*Pseudolarix*), however, the leaves are shed individually every fall; and the bald cypress (*Taxodium*) and the dawn redwood (*Metasequoia*) cast off small leaf-bearing twigs every season to remain leafless during the winter. Conifers have cones but these are never terminal on the main stem of the plant. The seed cones may be large and made up of dozens of cone scales. In a few genera, the seed-bearing scales are reduced to single ovules and they appear as if terminal on the secondary branches that bear them. However, with respect to pollen-bearing cones conifers are less diverse. All conifers have pollen borne in cones which are usually quite small.

**Uses.**—Conifers include some of the most useful plants aside from food plants. More than three-fourths of commercial lumber is obtained from species of pine (*Pinus*), Douglas fir (*Pseudotsuga*), spruce (*Picea*), bald cypress (*Taxodium*), redwood (*Sequoia*) and arbovitae (*Thuja*). In the south temperate zone,

*Araucaria*, *Agathis*, *Podocarpus* and *Dacrydium* are very important timber species. The wood of all conifers is classed as softwood, in contrast to the hardwood lumber obtained from broad-leaved angiosperms such as oak, walnut, birch, poplar, gum, elm, ash, maple, hickory, mahogany, etc.

The pines also yield resin, pitch, turpentine and various oils. Important resins are obtained from *Araucaria* and *Agathis* in the southern hemisphere. A large amount of coniferous wood from both hemispheres enters into the manufacture of paper as pulp.

Many of the species not sufficiently abundant for lumbering, as well as the economically important species, are planted for ornament in landscaping. The pines of the Mediterranean region and the cryptomerias of Japan are justly famous examples. The seeds of some species of pine furnish food for man and the seeds of all conifers are eaten by animals. Seeds of the Italian stone pine have long been esteemed as a delicacy and are exported to other countries. In the southwestern United States, the Indians regularly harvest seeds of the piñon pine for food and for sale.

**Distribution.**—Conifers are most often found in more or less moist habitats in hilly or mountainous areas. They frequently occur at high altitudes extending up to timberline where they form the characteristic *krummholz* (i.e., a belt of stunted tree growth). Four genera (*Taxodium*, *Glyptostrobus*, *Metasequoia* and *Pherosphaera*) occur in very wet places: lowlands, swamps, borders of lakes and rivers, etc. Another group includes those, such as *Juniperus*, *Cupressus*, *Abies*, *Pinus* and *Podocarpus*, which are large, wide-ranging genera. Their species occur in wet situations, mesic habitats and even extend into semidesert areas. The general restriction of the conifers to moist places may be brought about by their relatively poor (in comparison with the angiosperms) water-conducting systems.

If the distribution of the various genera is plotted on a map of the world it can be seen that they are strikingly concentrated in the mountainous areas around the Pacific basin and in the islands of the Pacific. They are rare as a group on the Atlantic and Indian ocean coasts.

About 30 genera are confined to the northern hemisphere and about 20 rarely get out of the southern hemisphere. Only three or four genera cross the equator with some of their species inhabiting both hemispheres. There is thus a distinct differentiation into a southern group and a northern group of genera. Paleobotanical evidence indicates that this distinction has existed since the late Paleozoic era. It also appears that the association of the conifers with mountainous areas and the Pacific basin is an old one as well.

**Families.**—Six families of Coniferales are usually recognized, although some botanists feel that there should be more or fewer. Some of the subfamilies are sometimes given family rank. Similarly some of the genera have been or may be subdivided as more evidence concerning their anatomy, embryology and chemistry becomes available. With this in mind, the numbers given for genera and species must be considered as tentative and dependent upon the authority consulted. The families considered here are: Pinaceae with 9 genera in two subfamilies, Araucariaceae with 2 genera, Taxodiaceae with 9 genera in two subfamilies, Cupressaceae with 18 genera in three subfamilies, Podocarpaceae with 7 genera in three subfamilies and Cephalotaxaceae with 1 genus (or 2 genera, if one problematical genus, *Amentotaxus*, is included in the family). In older works only two families were recognized: Pinaceae and Taxaceae. The proper disposition of the yews, Taxaceae, is a particular problem. Investigations have indicated that the Taxaceae probably never had ovule-bearing appendages aggregated into cones. In this way they differ from the conifers. Those Coniferales, which produce one or a few seeds (e.g., Podocarpaceae) often have the cones so reduced as to be unrecognizable as such. Anatomical studies show that these are cones and logically these plants are grouped with those from which they were probably derived rather than with those they superficially resemble.

**Stem Anatomy and Physiology.**—The stem of conifers follows the same structural plan as the dicotyledonous angiosperms. The embryo produces a small amount of primary tissue and continues to grow from the shoot tip upward and from the root tip

downward. There is a central pith surrounded by a circle of vascular bundles with xylem toward the inside and phloem toward the outside. Superimposed on this primary growth is growth in diameter—the result of the activity of a lateral meristem or cambium which arises between the xylem and phloem. This cambium produces secondary xylem toward the inside and secondary phloem toward the outside, with the result that the primary tissues are separated, the phloem crushed, the xylem buried within the ever increasing mass of secondary wood. A second cambium, the cork cambium, produces the bark, a secondary tissue which replaces the epidermis of the root and stem. This cambium is frequently renewed and, arising each time farther into the secondary phloem, it eventually abuts upon the active phloem. The living part of the tree then consists of a hollow shell composed of the two cambia, the active phloem transporting food and the active xylem conducting water with its dissolved minerals.

Annual growth rings are produced in the secondary wood deposited by the cambium. Coniferous wood differs from the wood of angiosperms in the absence of vessels. Vessels are cells of the xylem which have lost their end walls. Arranged end to end they form what are functionally long pipes. Only in the Gnetales among the gymnosperms are vessels developed. In the conifers water is conducted through long tracheids which communicate through bordered pits, each closed by a delicate membrane through which the water must pass. In addition to the tracheids there are wood rays composed of living cells, usually only one or a few cell layers thick, and these are bordered by ray tracheids in many Pinaceae. The wood rays also communicate with the tracheids by means of pits. The size, shape and arrangement of the bordered pits, whether they are in one or several rows, whether or not they are accompanied by thickenings of the wall called crassulae, and especially the character of the pitting in the cross fields where ray cells border on tracheids, are criteria that enter into the study of wood anatomy.

The wood of some genera of Pinaceae has resin canals which are ducts lined with resin-producing cells. In other families there are only resin cells, or cells containing other oils, and many types have resin passages in the cortex. *Pseudotsuga* has spiral thickenings in its tracheids in addition to the thick secondary cell wall. These and other anatomical features of coniferous woods have been studied extensively and have been organized into keys for the identification of species by wood alone. The chemical nature of the resins also can be used to identify some conifers as well. Studies of the chemistry of the various products secreted by these plants have added materially to our understanding of their interrelationships.

**Leaves.**—The simple leaves of conifers are characterized by their small size; e.g., the needle form represented by *Pinus*, *Cedrus*, *Tsuga*, *Picea*. The needlelike leaves are fitted by nature to prevent escape of water from the plant. Thus, these trees can retain their leaves in the winter, hence their common name of evergreens. The flat or angular linear leaves of *Thuja*, *Cupressus* and *Libocedrus* are appressed to the branches and have a single midvein. Leaves of the latter genera often have a prominent resin gland. The flat and comparatively broad leaves of some species of *Araucaria*, the leaves of *Agathis* and the leaves of the section *Nageia* of *Podocarpus* have several parallel veins. The largest leaves found in the conifers are those of *Podocarpus blumei*, which may be seven inches in length and nearly two inches broad; but with this exception, and the long needles of several of the pines, the leaves of conifers are relatively small. The leaves of most conifers show adaptations which reduce water loss, such as thick cuticle and few and modified stomata. The latter may be restricted to one or several lengthwise bands which are often visible as gray or white lines.

Many conifers have leaves that are polymorphic. The leaves of seedlings usually differ from the leaves of the mature tree. In some junipers, cypresses, etc., in which small leaves appressed to the stem are normal in adult plants, examples occur in which these leaves are replaced by longer, slender, needlelike leaves standing out almost at right angles to the branch. This condition is usually typical of the seedling stage. Such examples are often

seen in cultivation and often are termed *retinospora*, though the term does not denote a true genus, but merely the persistence of the juvenile form of a species belonging to any of several genera e.g., *Thuja*, *Juniperus*, *Cupressus*, *Chamaecyparis* and other trees of the same type.

In trees with resting winter buds the difference between the bud scales and the foliage leaves is always pronounced. When the winter buds have broken, the scars or the dried bud scales remain around the twigs and mark the growth of successive seasons. Some of those with naked buds also may show seasonal differences in the length of leaves produced along the shoots; e.g., *Araucaria*. The genera with flattened twigs usually have longer leaves on the edges of the twigs than on the sides. In the southern hemisphere there are many conifers of the genera *Dacrydium*, *Podocarpus* (section *Dacrycarpus*), *Acropyle*, etc., in which the green foliage leaves are dimorphic and even trimorphic so that when judged by the shape of the leaves alone, they are not always recognized as belonging to the same species.

The occurrence of long and short shoots is a characteristic feature of *Pinus*, *Cedrus*, *Larix* and *Pseudolarix*. In *Pinus* the needles occur in pairs, or in clusters of three to five (rarely only one, as up to eight) at the apex of small and inconspicuous short shoots of limited growth (spurs). The spur is enclosed at its base by several scale leaves and is borne, upon a branch of unlimited growth, in the axil of a scale leaf. The short shoots of the other three genera are stout spurs bearing an indefinite number of

needles and they are not sheathed with the leaves as are the spurs in pines.

A remarkable and unique leaf is found in the umbrella pine (*Sciadopitys verticillata*). These leaves are actually borne spirally in the axils of the scale leaves, but are restricted to apparent whorls alternating with regions of the twigs bearing only scale leaves. They are grooved and have two separate veins, suggesting an origin from a pair of needle leaves. A peculiarity of the leaves is the inverse orientation of the vascular tissue: each of the two veins has its phloem next to the upper, and its xylem next to the lower, surface of the leaf. This unusual position of the xylem and phloem is explained by regarding the needle of *Sciadopitys* as composed of a pair of leaves on a short shoot, fused by their upper margins (fig. 1).

In the genus *Phyllocladus* in New Zealand there are no green foliage leaves. In their place

FIG. 1.—CROSS SECTIONS OF SHOOTS OF CERTAIN CONIFERS: (A) "NORMAL" SHORT SHOOT OF PINUS. (B) "DOUBLE NEEDLE" OF SCIADOPITYS. (C) OVULIFEROUS SCALE OF LARIX AND PINUS.

and resembling leaves, are flattened branches (phyllodes) which are borne in the axil of small-scale leaves.

The leaves of most conifers are arranged spirally, but in one entire family, the Cupressaceae, they are always opposite, in pairs or in threes. This applies also to the monotypic genus *Microcarpus* and to a few species of *Podocarpus*, but not to other conifers.

While the vegetative structures alone are not considered dependable as a basis for the classification of conifers, they may be very useful diagnostically. A special example is provided by the stomatal structures, including the number and arrangement of subsidiary cells and other cuticular features. It is possible to place all or nearly all living conifers into their families and genera on the basis of cuticular structures. In many fossils, the outward size and form and the details of cuticular structures are that remain. The true classification of these fossils without reference to productive parts may thus be determined and they may be compared with the living genera.

**Reproductive System.**—The basis for classifying the conifers as a group, however, is the reproductive system. Thus in order to fully understand the relationship of one plant to another, the botanist must know the structure of the cones as well as details of the development of the male and female reproductive organs and of the embryo.

The conifers, like other gymnosperms, have an alternation of generations, and the dominant generation that is seen, say, in a pine or a spruce, is the sporophyte. Sporophytes of conifers have unisporangiate cones; that is, one kind of cone will produce spores that develop into the male gametophyte (male gamete-producing plant), while another will produce spores that give rise to the female gametophyte. These are the staminate or pollen-bearing cones, and the ovulate, or seed-producing cones, respectively. The male gametophyte is the pollen grain, while the female gametophyte is produced inside the ovule and never escapes from the sporophyte. Monoecious conifers have both kinds of cones on the same plant; dioecious conifers have the two kinds of cones on different plants.

A typical staminate cone consists of a central axis, bearing from six to many scalelike appendages. These are arranged as the leaves; i.e., they are spirally arranged except in the Cupressaceae where they are opposite or whorled. The scale is composed of a slender stalk terminating in an upturned blade and bearing from 2 to 15 pollen sacs or sporangia on its lower surface. The larger number of sporangia (6 to 15) is characteristic of *Araucaria* and *Agathis* in which the sporangia are also peculiar in their large size and in being long, slender and freely pendent. In the pine and podocarp families, there are always only two sporangia attached lengthwise along the stalk and usually a small pointed or rounded blade at the tip. Taxodiaceae and Cupressaceae have various numbers of pollen sacs, usually in excess of two. The sporangia are opened by longitudinal, occasionally by oblique or transverse, slits. An assortment of pollen-bearing scales of various types from different genera is shown in fig. 2.

In the origin of sporogenous or spore-producing tissue which gives rise to the tapetum (nutritive cell layers for the spores) and the pollen mother cells, the conifers agree with the cycads and ginkgo. Pollen mother cells undergo meiosis, a special type of cell division which results in four cells, each with half the number of chromosomes in the mother cell. Such a reduction division must always occur prior to the formation of gametes, since the fusion of gametes doubles the chromosome number. The sporophytic and gametophytic number of chromosomes are symbolized by  $2n$  and  $n$ , respectively. After the spores in a quartet have become separated from one another, they develop a double spore coat consisting of the exine and intine. The outer layer or exine includes, in all Podocarpaceae (except *Saxegothaea*) and in most of the Pinaceae, a pair of bladderlike appendages which dry out as wings. The shape and structure of the exine often are suffi-

cient to permit identification of the plant on this basis alone.

Division of the spore nucleus begins the formation of the male gametophyte or pollen grain and its mode of development is an indication of evolutionary advancement. It is believed that those with a large number of sterile cells, or prothallial cells, are more primitive in this respect (that is, more like the ferns and club-mosses).

Stages in the development of pollen grains in pines are shown in fig. 3. Here the spore divides twice to form two abortive prothallial cells which become flattened against the wall while the intine is still forming. Pollen that has not matured to this stage within the pollen sac will not germinate normally. The cell that remains (D) is an antheridial intial, which forms, when it divides again, a tube nucleus and a generative cell. The pollen of pine is shed in this condition and is carried to the ovulate cones by wind. In several genera of Pinaceae, the generative cell divides to form a stalk cell and body cell before pollination, but otherwise all subsequent development takes place after the pollen grain becomes lodged on the nucellus of an ovule.

In Araucariaceae there are many more prothallial cells and these usually persist. In *Araucaria* there are about 15 prothallial cells, the nuclei of which persist after the walls between them disappear; subsequent divisions of these result in 20 to 44 free nuclei which are present in later stages in the pollen tube.

The Podocarpaceae include several genera in which more than two or three prothallial cells are formed and these cells or their nuclei may persist. *Pherosphaera* appears exceptional for no traces of prothallial cells have been found. In several other genera, where only two prothallial cells are formed, at least one of these persists.

No prothallial cells are produced in Taxodiaceae and Cupressaceae. Most of these shed their pollen with only two nuclei formed: the tube nucleus and the generative nucleus or generative cell. Only a single nucleus is found at the time of pollination in nine species representing five genera of Cupressaceae. In 11 species belonging to other genera in this family, as well as in all Taxodiaceae, the pollen grain contains two nuclei at the time of pollination.

The pollen grain is to be regarded as a separate, individual, though very small, plant which will produce the male gametes. After it has arrived at the nucellus of the ovule, it produces a pollen tube through which the various nuclei and cells are carried toward the female gametophyte. In the events that take place in the nucellus, those that follow the formation of the tube nucleus are uniform in all conifers. The generative cell usually gives rise to the stalk and body cells (fig. 3[G]). The body cell divides to form two male gametes or only the nuclei of the two male gametes,

FIG. 2.—SCALES FROM THE POLLEN CONES OF VARIOUS CONIFERS

shortly before fertilization (fig. 3[H]).

Where both male nuclei may function in the fertilization of eggs of neighbouring archegonia, the male cells are equal in size. In the remaining genera of conifers, in which only one of the pair of male cells or nuclei is functional, the second male cell or nucleus is frequently much smaller than the functional one.

A large number of cells and nuclei formed in the pollen grains is considered a primitive condition, characteristic of the more primitive families, while few cells or nuclei in the pollen grains is considered advanced. Since all conifers form the stalk cell, they have at least four nuclei formed in the pollen grain, while angiosperms commonly omit the stalk cell and have only three.

The seed cones of pines are among the most familiar conifer cones. They have numerous scales firmly attached to an axis and on each a pair of seeds is formed. A mature cone appears simple enough, but when cones are examined at the time of pollination, they are found to be much more complicated than the pollen cones. The scales which bear the ovules appear inserted in the axil of a bract which is as long as the scale or longer when the cone is young. All members of the pine family including spruces, firs, larches, etc., have this peculiar structure. In many firs, and notably in *Pseudotsuga* (Douglas fir), the bracts are long and project between the scales at maturity. In all pines, and in most of the other genera, the bracts remain rudimentary or are short and sometimes difficult or impossible to find in a mature cone. Fig. 4 shows an assortment of ovuliferous scales with subtending bracts, representing different genera of Pinaceae.

The ovuliferous scale has its vascular bundles in an inverted position with the phloem above the xylem. There is also a question as to whether this structure, if in any way comparable to a leaf, represents a single unit or is composed of several fused parts. Is it like the leaf of a fern bearing several sporangia on its surface, or does it represent as many sporophylls as there are ovules found on its surface? The morphological nature of the ovuliferous scale has been discussed by botanists for more than a century, during which proponents of one hypothesis or another have called it a carpel, a placenta, a flattened axillary shoot, a ligule, an outgrowth from the chalazal end of the ovule, etc. There has long been general agreement that the bract is homologous with a leaf, but leaves do not bear other leaves in their axil without the formation of at least some axis.

MODIFIED, AFTER HIRMER AND STRASBURGER

FIG. 5.—LONGITUDINAL SECTIONS OF CONE SCALES OF VARIOUS GENERA AND SPECIES OF CONIFERS

The question appears to have been resolved satisfactorily as a result of research on the morphology and anatomy of recent and fossil members of the Coniferales and of the now extinct Cordaitales (see PALEOBOTANY). Evidence shows that the ovuliferous scale is an axillary shoot, highly modified and bearing sterile scale-like appendages and fertile ovule-bearing appendages. The latter were never in their evolutionary history leaflike. Each ovule represents such an appendage and the remainder of the scale is composed of fused sterile appendages. The whole structure is borne in the axil of a bract and thus the cone is seen to be a compound structure in contrast to the pollen cone.

In the Pinaceae the ovuliferous scale and the bract are always separate. In nearly all other families the scale is united with the bract along its entire length to form the cone scale. In some genera the scale becomes longer than the bract, in others the bract is the longer element. The two component structures may be recognized by the position and the orientation of the vascular bundles which are inverted in the ovuliferous scale. Fig. 5 shows diagrams of the fused cone scales in *Araucaria*, various genera of Taxodiaceae and Cupressaceae, with their opposed vascular bundles. In the Araucariaceae the scale and bract are fused into a single member and this double structure bears only a single seed. The so-called ligule of the scale in *Araucaria* is the tip of the ovuliferous scale while the longer tip is the end of the bract. Scales of two species of *Araucaria* are shown in fig. 5. In the fossil *Araucarias* (*Proaraucaria*), the scale and bract are not completely fused as shown in fig. 6(C).

In the seed cone of *Sciadopitys* (fig. 5) the bract and scale are fused nearly to the exposed end of the scale, where these members, both of them greatly thickened, are distinct and may be recognized externally. Here the bract has only a single vascular

bundle while the scale has a bundle system that is branched, with strands leading off to the five or nine or more ovules borne on this structure.

In other members of the Taxodiaceae with which *Sciadopitys* is usually included, there is a more complete fusion of the bract and scale. In *Cunninghamia* the ovuliferous scale is only half as long as the bract, its tip forming a small thin ligule above the attachment of the seeds. The opposed bundles appear fused at the base, but diverge distally, in Cupressaceae. In those genera with woody cones the compound nature of the cone scale may be recognized, as is shown by the selection represented in fig. 5.

In the Podocarpaceae the ovuliferous scale usually becomes fleshy and is known as an epimatium. It may surround the ovule only at its base, or partially cover the seed. In most species the epimatium completely surrounds the seed, forming an outer integument as shown in fig. 7 (A) and (B). However, the vascular bundles of this outer member have the orientation that would be expected in the ovuliferous scale. Here the cone itself is reduced to an axis bearing several sterile bracts and ending in the ovule. The axis and its scales also become fleshy and swollen forming a receptacle on which the seed is borne.

The ovule, in the seed plants, is the structure in which the female gametophyte is produced by the germination of a spore which arises by meiosis of certain specialized cells in the nucellus, a tissue equivalent to a sporangium. The nucellus is open to the outside only through a narrow canal called the micropyle. The ovules of conifers are borne on the tip of their stalks, but since the appendages are inverted and frequently fused with the bract, the ovules and seeds appear on the upper surface of the cone scale. As stated before, this interpretation is supported by the inverse orientation of the vascular bundles in the ovuliferous scale as well as by the fossil evidence. The Pinaceae always have two ovules per scale. In some families there are as many as eight or nine, in others the ovules occur singly.

The micropyle is directed toward the main cone axis in Pinaceae, Araucariaceae, most Podocarpaceae and in some genera of the Taxodiaceae. In the remaining Taxodiaceae, in the genera *Dacrydium*, *Phyllocladus*, *Acropyle* and *Pherosphaera* (all belong to the Podocarpaceae) and in the Cupressaceae and Cephalotaxaceae, the ovules and seeds are erect. In the earliest stages of evolution the ovules were erect, but there is abundant evidence to indicate that in many of the fossils, even in the Paleozoic, inversion of the ovules had occurred (see fig. 6[A] and [B]). Furthermore, the families of living conifers that have erect ovules and seeds are represented by fossil ancestors only in more recent geological rocks. It is reasonable to suppose, therefore, that the erect ovules in living forms developed from the inverted types.

The erection of the ovule was accompanied by a great reduction in the seed cone. The cones having the largest number of scales always have inverted seeds; it is only among those with few scales per cone or with the cone reduced that erect seeds are found.

The young ovulate cones appear on the plant at the time that the pollen is ready to be shed from the pollen cones. They are small and loose and, with their scales spread apart so that the pollen may lodge on any part of the cone including the ovules, have a bristly appearance. The transfer of pollen is accomplished by wind. Ultimately some of the pollen grains find their way to the nucellus within the ovule. Thus we have the male gametophyte which will produce the male gametes brought to the vicinity of the female gametophyte within the nucellus. The pollen tube of the male gametophyte must then grow through the nucellar tissue to bring the gametes

FIG. 7.—OVULES OF *PODOCARPUS TOTARRA* AFTER FERTILIZATION, SHOWING DEVELOPMENT OF EMBRYO (SEE TEXT)

together. Entrance to the ovule is gained through the micropyle and accomplished by a pollination drop mechanism essentially like that in cycads. However, the droplet method of gaining entrance is not universal. For example, in *Larix* and *Pseudotsuga*, the lips of the integument become stigmatic on the inner surface and catch the pollen of the exposed surface spread apart at this time. In a few days the stigmatic lips roll inward to close the micropyle and this transfers the pollen to the inside. In *Saxegothaea* the nucellus enlarges and protrudes from the micropyle and the pollen then falls directly on its surface.

The greatest departure from the usual pollination mechanism is shown by *Araucaria*, which varies in the direction of angiosperms, for here the pollen falls on the ligule formed by the tip of the ovuliferous scale (see fig. 5) and germinates there, growing for a considerable distance before reaching the ovule.

However the details differ in the various genera, the pollen tube always approaches the egg by digesting its way through the nucellus.

After pollination the micropyle usually closes; the ovuliferous scales thicken slightly so that the entire cone is closed and remains shut until the seeds are matured. The ovules that were pollinated, along with the cones, enlarge fully before fertilization (i.e., the fusion of gametes), but in the pine and several other genera, this growth does not begin until a year or two after pollination.

Although the distance traveled by the pollen tube is usually very short, the process requires several months even in the annual genera such as *Abies*, *Picea*, *Larix*, *Pseudotsuga*, *Keteleeria* and *Tsuga*, the Cupressaceae and most Taxodiaceae. Pines are bi-

ennial, requiring 14 to 15 months (in a few triennial species, 26 to 27 months) to complete pollen tube growth. *Araucaria* and *Sciadopitys* are also among the biennial types, while in *Cedrus* the period is five to six months, extending from fall till spring of the following year.

The internal anatomy of the ovule in *Pinus* is shown in the series of stages in fig. 8. Fig. 8(A) shows a section through the ovule at the time of pollination, with a spore at its centre and a few grains of pollen on the nucellus. The micropyle soon closes and the cone enlarges very little during the first season, during which the cones also remain small. Fig. 8(B) shows the winter condition in a pine with the female gametophyte enlarged slightly in a free-nuclear stage of development. The pollen grains have germinated but have not penetrated far into the nucellus. These structures begin to enlarge only in the year after pollination, when the cone grows rapidly and reaches its full size within a few months. The ovule of a cone that has not fully enlarged is shown in fig. 8(C), with two of the several archegonia fully developed and with several pollen tubes approaching them at about the time of fertilization. The archegonia are the female sex organs in each of which an egg is produced.

The pollen tube has a tube nucleus, a stalk and a body cell. Shortly before fertilization, the body cell divides to form two male nuclei, both of which may enter the egg, but only one of which unites with the egg nucleus in fertilization (fig. 3[H]).

The female gametophyte, like the male gametophyte, is a haploid generation: it contains half the number of chromosomes found in the sporophyte and originates from a spore produced by meiosis in the sporogenous tissue of the ovule. Of the four spores produced, only one survives to germinate and form the gametophyte;

FIG. 9.—UPPER PORTION OF OVULE OF *BIOTA*, SHOWING ARCHEGONIAL COMPLEX IN RELATION TO POLLEN TUBES JUST BEFORE FERTILIZATION

necks composed of from four to eight cells, sometimes situated in several tiers, and a distinct jacket of nutritive cells surrounding the large egg. Between the egg and the neck of the archegonium a cell is produced which is called the ventral canal cell and which disappears by the time of fertilization. In the other families of Coniferales only ventral canal nuclei are formed, while some genera appear even to omit formation of the ventral canal nucleus. The Pinaceae are considered to be primitive in this respect, while the forms without the ventral canal nucleus are the most advanced those with ventral canal nuclei are intermediate. In all cases the ventral canal cells or their nuclei are regarded as vestigial relics of the fern type of archegonial formation, and they have no known function.

In Taxodiaceae, with the exception of *Sciadopitys*, and in all Cupressaceae, numerous archegonia are grouped into an archegonial complex (fig. 9). In this close grouping they are separated from one another by a single cell wall and the entire group may be surrounded by a common archegonial jacket. Thus it is possible for both male cells, from a single pollen tube to fertilize two adjacent eggs, two pollen tubes to fertilize four eggs, etc., a common occurrence in both Taxodiaceae and Cupressaceae.

In the *Sequoia* group of the Taxodiaceae and in the *Callitriche* group of the Cupressaceae, the archegonia are situated laterally on the gametophyte (fig. 10). Here the pollen tubes fertilize eggs that are situated about halfway down the sides of the female gametophyte. While both of these groups, belonging to different families, have lateral archegonia, they are not necessarily closely related on other grounds and this resemblance may be the result of convergent evolution.

The male nuclei enter the archegonia by passing through a narrow opening between the neck cells. The union of the male nucleus with the egg nucleus has been observed in many species of conifers. In most instances the male nucleus is smaller than the egg nucleus, but the difference in size may be due only to the amount of nuclear sap present in the respective nuclei at the time of fertilization. Each contributes the same number of chromosomes to restore the diploid or sporophytic number of chromosomes in the zygote. The amount of chromatin is probably the same,

FIG. 10.—OVULES OF (LEFT) *SEQUIADENDRON* AND (RIGHT) *ARISTOTROBUS* AT TIME OF FERTILIZATION

FIG. 8.—DEVELOPMENT OF OVULE OF *PINUS* FROM NEAR THE TIME OF POLLINATION TO MATURE EMBRYO (SEE TEXT)

for when a difference in size has been noted, the male nucleus usually stains more deeply. After the male nucleus contacts the female nucleus, they combine slowly and the nuclear membranes that separate them gradually disappear. The two components of the fusion nucleus may be recognized for some time; they have been observed to enter the prophase of the first mitotic division separately, as the resulting chromosome groups are sometimes recognizable in the metaphase of the first division.

**Development (Embryogeny).—**The type of embryogeny, or mode of formation of the embryo, is one of the most important features in serious study of the Coniferales. Unfortunately the processes which go on are complicated and unlike those in animals so that they are difficult to understand. It is necessary to describe them in some detail, however, in order to present a complete picture of the evolutionary relationships in this important group of plants. The embryogeny of conifers shows considerable diversity. Nevertheless, it appears to be almost constant within a particular genus. The only exception is the genus *Podocarpus*, but in this large taxon the same rule holds when applied to the subgenera or sections of the genus considered as units. The differences in embryogeny between the various genera occur principally in their early stages of development.

A common feature in seed development in gymnosperms is the production of more than one, or even many embryos at the beginning of seed development. This may come about in two ways: since there is more than one archegonium, and hence egg, several zygotes (fraternal twins) may begin development; or early in embryogeny, the zygote, called a proembryo at this stage, may split to form several embryos (identical twins). Usually both types of development occur at the same time, but of the many embryos formed only one survives to maturity in the mature seed.

Multiple embryo formation or polyembryony is universal among conifers. Simple polyembryony would be found possible in all genera with more than one archegonium to be fertilized. However, in addition to this, the zygotes of most conifers give rise to several embryos coming from each fertilized egg through cleavage polyembryony. The embryogenies of about 37 genera are known sufficiently to warrant the statement that cleavage polyembryony is found in a great majority of the conifers; it is found in some modified form in over half of the genera which have been examined.

After fertilization the zygotic nucleus undergoes two successive divisions near the centre of the eggs in the Pinaceae which will be described as a typical form from which deviations may be mentioned later. These nuclei migrate to the lower part of the egg where they undergo another division before walls begin to form between them. The upper of the two tiers of cells which result and which have incomplete walls undergoes another division forming a new tier of cells. This tier is the rosette, and it has an open tier of incompletely walled cells above it, the relict nuclei of which soon disintegrate. The eight cells (fig. 11[A]) with complete walls arranged in two tiers are each the potential origin of a separate embryo in all genera of this family, with the exception of *Pseudotsuga* in which the four rosette-forming nuclei migrate and disintegrate in the upper end of the egg. Another division of cells in the lower tier forms a tier of suspensor cells between the lowest tier and the rosette tier. This is followed by the elongation of the suspensor tier, thus ending

what has been called the prostage of the embryo.

Subsequent development is accomplished by a series of divisions of the cells giving rise to new cells in regular succession by division of the apical cells below. The new additions to the suspensor are called embryonal tubes which gradually build up a secondary suspensor as they in turn elongate. A prosuspensor, to be described for many of the conifers in other families, is not formed in the Pinaceae.

From these early stages onward, the different genera of Pinaceae vary somewhat. In *Pinus* and *Cedrus* a separate embryo is formed from each of the eight walled cells of fig. 11(B). In *Pinus* the four lower embryos become separated from one another much sooner than in *Cedrus* (fig. 11[E]). In *Tsuga* the lowest tier of cells forms four embryos as in *Pinus* and *Cedrus*, but the cells of the rosette tier, with the possible exception of *Tsuga mertensiana*, usually disintegrate without forming embryos. In *Keteleeria* the rosette tier forms rudimentary embryos of several cells. In *Pseudotsuga* these cells usually remain undivided, but between the rosette and the apical tier, other embryo-forming units may originate in both of these genera.

In *Abies*, *Larix* and *Picea* the rosette cells usually collapse without further subdivision, while the rosette is not formed in *Pseudotsuga*. In all of these last four genera the lower embryonic cells appear to be combined into a single embryo, giving the appearance of simple polyembryony. However, J. M. Schopf has shown that in *Larix*, at least, and probably in some of the others where neither the suspensor cells nor the apical cells become separated from one another, the units represented by the four vertical rows of cells undergo an intense competition growth during later stages of the embryogeny, until one of the apical cells finally overtops the others, with the result that only one of them gives rise to the tissue that enters into the meristem of the surviving embryo.

The last stages of development in the embryogeny of the Pinaceae are more uniform in all genera, but there are differences in the number of cotyledons. This number varies even within a species and is usually in excess of two. In *Pinus* and *Cedrus* there are usually 7 to 12 cotyledons, in *Picea*, *Abies*, *Larix* and *Pseudotsuga*, 5 to 7. Only in *Tsuga* and *Keteleeria* the number falls to four, three and two cotyledons.

In Araucariaceae a very different type of embryogeny is encountered. In the proembryo of *Agathis* and *Araucaria* at least 32 free nuclei are formed and these remain near the centre of the egg where they become organized into a small sphere of cells. A group of cells near the centre of this sphere gives rise to the embryonic meristem; those situated near the periphery on the side toward the neck of the archegonium elongate together to form a massive prosuspensor; and those situated on the side toward the lower end of the archegonium form a multicellular cap. The latter is protective and is cast off later when the suspensor structure has become greatly elongated and twisted. No cleavage polyembryony occurs, but several archegonia may be fertilized corresponding to the number of embryos present in the gametophyte. The surviving embryo of the seed has four cotyledons in some species of *Araucaria*, two in others and in *Agathis*.

In *Sciadopitys* the embryogeny follows a different pattern, resulting in an extreme example of cleavage polyembryony. The only thing in common with the Araucariaceae is the fact that there are 32 free nuclei formed in the proembryo before walls appear between them, but these are all situated in the lower end of the egg. They become organized into three or four tiers or regions, with the lowest group composed of 12 to 18 or more embryonic cells somewhat irregularly arranged. Above this is a tier of seven to nine cells which elongate forming a prosuspensor. Above the prosuspensor there may be a layer of rosette cells or this may be represented only by a few cells or entirely absent, with a layer of relict nuclei that disappear at the top. The terminal or lower group of embryonic cells is each a separate embryo initial that develops only after the prosuspensor has become long and twisted (see fig. 12). Each of these cells divides to form two cells, an apical embryonic cell and a primary suspensor cell, though the embryonic cell may divide again before the latter

FIG. 11.—DEVELOPMENT OF PROEMBRYO OF *PINUS* (see TEXT)

elongates. Elongation of the primary suspensors pushes the individual units deep into the gametophyte, where, after a period of intense competition, one or a few of them survive the later stages. Usually only a single one remains to mature as the embryo of the seed in the final stage.

Rosette cells may give rise to embryos in the region above the prosuspensor so that the number of embryos coming from a single zygote may exceed two dozen; this potential number is doubled or trebled if the eggs in two or three separate archegonia are fertilized. The matured embryo only has two cotyledons.

The other Taxodiaceae differ somewhat from *Sciadopitys*. In *Cunninghamia*, *Taiwania*, *Cryptomeria* and *Taxodium* there are eight free nuclei when walls are formed in the proembryo. Usually there is no group of rosette cells and there are fewer cells in the prosuspensor and fewer embryonic cells. The single-celled primary suspensor is omitted from the individual embryos, but in its stead a massive group of several embryonal tubes elongate as a massive secondary suspensor. The mature embryo has two cotyledons in *Cunninghamia* and *Taiwania*, three in *Cryptomeria* and four to six in *Taxodium*.

The *Sequoia* group within the Taxodiaceae have embryogenies that differ from each other markedly. Both of these genera have archegonia situated laterally on the gametophyte. They are small, numerous and grouped together (see fig. 10). The embryogeny of *Sequoiadendron* would correspond closely with that of *Sciadopitys* except that the proembryo forms only eight free nuclei before walls are formed between them, and the prosuspensor is a much weaker and more ephemeral member. Cleavage polyembryony results in a smaller number of embryos, even when the rosette embryos are included. The mature embryo usually has four cotyledons. In *Sequoia* on the other hand, the first division of the zygote is followed by the formation of a cell wall between the nuclei, another division results in a four-celled proembryo from which no prosuspensor is formed, but usually four individual embryos borne on primary suspensors emerge. The mature embryo of the seed has two cotyledons in the majority of cases. While there appear

FIG. 12.—EMBRYOGENY OF *SCIADOPITYS* (see TEXT)

FIG. 13.—EMBRYOGENY OF A SINGLE ZYGOTE OF *BIOTA* (see TEXT)

suspensor, with four or more cells arranged tetragonally below, each giving rise to an embryo borne on a primary suspensor. Several species of *Cupressus* have three to four cotyledons, other species two cotyledons, the number found in the other three genera.

*Thuja* has an embryogeny which follows a development very

similar to that of the above genera up to the stage shown in fig. 13(A). However, there is no cleavage in the embryo, the parts hold together as a single unit so that only one embryo is produced from each zygote.

In the group of genera represented by *Actinostrobus*, *Callitris* and *Widdringtonia* the archegonial groups are situated laterally on the female gametophyte and are very small and numerous (see fig. 10). The proembryo forms walls after the second division of the zygote and there are about four embryo initial cells plus a few inactive cells in each archegonial unit. There is no prosuspensor. The four individual embryos coming from each zygote develop independently on the ends of the primary suspensors followed by secondary suspensors; in the matured seed the embryos are dicotyledonous.

A fourth type of embryogeny in this family is found in *Juniperus*. The early stages agree with the embryogeny of *Biota* up to the stage shown in fig. 13(A), with the tier of prosuspensor cells elongating much more, followed by an elongation of the lowest tier of embryonic cells. The cells of the lowest tier cut off small cells at their tips after elongation, and may repeat this process several times, with some of the cells dropping out at each step. Finally an embryonic initial cell is formed from which an embryo develops in the usual fashion.

In the Cupressaceae there is nearly always cleavage polyembryony, *Thuja* being the exceptional genus, with *Thujaopsis* somewhat intermediate, for in it cleavage polyembryony is greatly restricted.

Podocarpaceae have a variety of types of embryogeny which correspond more or less to the different genera and to the major subdivisions of the genus *Podocarpus*. Some species have 32 free nuclei formed in the proembryo before walls are formed, the majority of species of *Podocarpus* and other genera in the family have 16 free nuclei, and several species are known in which only 8 free nuclei occur at this time. All of them have prosuspensors which have from 3 or 4 to 20 or more cells that elongate, none of them have primary suspensors (single-celled suspensors), but form a massive secondary suspensor which follows the prosuspensor. There are definite embryo initial cells organized in the proembryo and these are usually binucleate through a considerable period of this stage of the embryo. The forms with 32 free nuclei in the proembryo and with numerous binucleate embryonic cells (considered to be the most primitive types) have cleavage polyembryony in reduced form, while a number of species in different groups have attained simple polyembryony. The latter include *Phyllocladus* in spite of numerous binucleate cells, and *Podocarpus totara*, *nivalis*, *P. hallii* and others, in which only a single binucleate cell is borne at the end of the prosuspensor (see fig. 7[B] and [C]). Many of the embryogenies in this family are known only in a few stages of development. The embryos have two cotyledons when the seeds are ripe.

It can be seen from the above discussion of embryogeny in the conifers that there is indeed a wide variety of types of development, some complicated and bizarre. It should also be clear, however, that information of this sort can aid materially in the understanding of interrelationships in the conifers.

The less obvious features of development, together with the details of gametophyte formation, often are more important than the superficial external characteristics of the sporophyte in deciding which genera are primitive and which advanced or in building systems of classification.

With the production of the embryo—the new individual of the sporophytic generation—the life history of the conifer has completed its full cycle and the process begins again when this individual undergoes meiosis to produce the spores giving rise to a new generation of gametophytes.

See GYMNOSPERMS and separate articles on specific conifers. See also references under "Conifers" in the Index volume.

**CONINGHAM, SIR ARTHUR** (1895–1948), British air marshal, was born Jan. 19, 1895, in Brisbane, Austr. After studying at Wellington and Victoria colleges in New Zealand, he joined the New Zealand army in 1914, serving in the infantry and later in the cavalry in Samoa and Egypt (1914–16). Although dysentery and typhoid fever forced him out of the dominion army in 1916, he joined the royal flying corps later the same year and served throughout the remainder of the war.

Shot down twice in action and once wounded, he was awarded the distinguished flying cross and given a permanent commission in the Royal Air Force in 1919. After World War I Coningham remained with the R.A.F. as a flight lieutenant and saw duty in Iraq as a squadron leader. In 1925 he was awarded the air force cross for leading a 5,600-mi. contest flight from Cairo to Nigeria which opened a trans-African route used in World War II to supply aircraft to the middle east, the U.S.S.R. and India. Later he served as an instructor in England at the R.A.F. college and Central Flying school and as air commander of a bomber group in England until 1941.

Appointed air vice-marshal in 1941, he commanded the R.A.F. and gave support to the British 8th army during the Allied offensives in Libya (1940–1942). In 1943 he participated in the Allied drive in Tunisia.

He commanded the 1st tactical air force of the R.A.F. in the Mediterranean (1943–44), and on Jan. 25, 1944, was selected as commander of the 2nd tactical air force of British and U.S. units which took part in the Normandy invasion. In that campaign he successfully carried out his doctrine of concerted use of air power and land power.

After 1945 Coningham was commander in chief of the Flying Training command of the R.A.F. (he was made air marshal in 1946) until his retirement in 1947. In 1942 he was created a knight commander of the Order of the Bath and in 1946 a knight commander of the Order of the British Empire. He died at sea on Jan. 30, 1948, in an air crash on a flight from the Azores to Bermuda.

**CONINXLOO, GILLIS VAN** (1544–1607), Flemish landscape painter, whose work represents the gradual transition from the fantastic conception of landscape of the 16th century as seen in the early work of Paul Brill to the realistic representation of the 17th. He was born Jan. 24, 1544, probably at Antwerp, and studied under Lenaert Kroes and Gillis Mostaert. After a period of travel in France he returned to Antwerp in 1570 and was made a member of the guild of painters. He had to leave his home again in 1585 to escape from religious persecution, and stayed at Frankenthal in Germany until 1595 when he settled in Amsterdam. He was buried in Amsterdam Jan. 4, 1607.

The development of Coninxloo's style is often described in three periods which somewhat correspond with his residence in Antwerp (1570–88), Frankenthal (1588–95) and Amsterdam (1595–1606). The transition is characterized by the gradual replacement of the deliberately composed landscape fantasies of his early period with his later, more naturalistic works in which the colour is blended into a harmonious atmospheric tone.

**CONJUNCTION**, a general term signifying the act or state of being joined together. It is used technically in astronomy and grammar. In astronomy two bodies are said to be in conjunction in right ascension, or longitude, when they have the same right ascension or longitude. The conjunction of Mercury or Venus with the sun is "superior" when the planet lies beyond the sun and "inferior" when the planet is between the earth and the sun. For use of the term in grammar, see GRAMMAR.

**CONJUNCTIVITIS** is inflammation of the conjunctiva, the thin mucous membrane lining the eyelids and extending over the globe to the limbus of the cornea. Like the mucous membrane of the nose, the conjunctiva is subject to inflammations produced by chemical irritants (e.g., smog), allergy (e.g., hay fever), bacteria, viruses and, occasionally, fungi and rickettsiae. Most in-

flammations of the conjunctiva are exogenous, but a few are endogenous by way of the blood stream. Conjunctivitis varies in severity from mild irritation (e.g., chronic catarrhal conjunctivitis) to severe, incapacitating forms (e.g., trachoma, ocular pemphigus, gonorrheal ophthalmia), which are accompanied by corneal inflammation and lead to scarring and visual loss. See also EYE, HUMAN; *Diseases of the Eye*. (P. T.)

**CONJURING**, the art of entertaining by pretended performance of those things which cannot be done. The conjurer is an actor who, to perform his feats, combines psychology with manual dexterity, frequently with mechanical apparatus. The two most common terms for the art, conjuring and magic, had in their earlier meanings association with devils, spirits and unholy powers. (See WITCHCRAFT.)

In the 20th century a more enlightened public, while recognizing intellectually that these apparently supernatural effects are, in reality, achieved by natural means, is, nevertheless, still dominated emotionally to some extent by the superstitions and fears of the unknown common in the past. The audience is, in short, usually willing to indulge in the prime requisite for the enjoyment of any form of theatrical entertainment—a "suspension of disbelief." It is an important part of the skill of the conjurer to nurture, through an adroit use of audience psychology, this predisposition to be fooled and amazed. This could be called showmanship.

Conjuring does not depend upon the quickness of the hand deceiving the eye. The newer terms, legerdemain, prestidigitation, sleight of hand, used to identify the art are questionable, since they suggest rapidity of movement and absence of equipment. Only in a minority of feats does the magician attempt to deceive the eye. He designs his tricks primarily to fool the minds of his audience, and to achieve this deception he usually depends upon apparatus and the use of natural physical and chemical phenomena. The magician so presents his work that the mind of the observer will take no notice of a great many things which his eyes can see. This focusing of attention of the audience on some actions so that others will be disregarded is called, by magicians, misdirection, a term of doubtful accuracy, since the conjurer directs attention toward one action rather than away from another.

A magician's manual operations, though not performed rapidly, require great deftness of touch and complete certainty of action. Independent use of the fingers and other unusual hand and arm movements are used in many tricks with the added handicap of each having to appear to be entirely normal. The magician's dexterity, unlike the musician's, is similar to the surgeon's in the type of deftness. Unlike the surgeon, the magician also must keep in mind the appearance of his movements. The magician is like the musician only in that he must have precision of time and exactness of rhythm.

Apparatus is of three types: (1) equipment which is exactly as it appears to the audience; (2) equipment which, secretly, has been prepared to aid the performance of the trick without altering its appearance; (3) equipment which is hidden from sight and used without the knowledge of the audience. Among those feats dependent upon apparatus some require but one type, while others need a combination of two, or even all three forms.

While tricks vary greatly, about 80% of the success of a conjurer's performance depends upon the use of psychology, 10% upon skilled manipulation and 10% upon the use of equipment. What makes an exhibition of mysteries effective is the agreeable personality of the conjurer and the timing, naturalness and smoothness of his performance.

A performance of the impossible is not only an intriguing show, but one which can be understood and enjoyed by all types of people of every country. Magic is an art of the theatre which is completely international. Most of the old and basic feats in magic are performed by the magicians of all nations, and, while slight variations exist in performance or equipment, the underlying principles are identical. It is unlikely that these basic tricks were taken from one land to another, but, rather, that they were developed locally, and the methods were alike because each nationality adopted the most simple means of performance. As magicians advanced through the ages, different

and more elaborate feats of magic were devised in various countries. In the 19th century, magicians of the world began interchanging their mysteries so that more and more oriental feats came into the programs of occidental performers, and eastern conjurers augmented their shows with the tricks of their western colleagues.

**Early History.**—Many scholars have written of the methods for the tricks shown in ancient times by the pagan priests of Egypt, Greece and Rome. It is known that optical illusions were used, apparently to bring forth divinities; that tubing was used to carry the voices of hidden humans, thus giving the effect of speaking idols; and that a variety of mechanical contrivances were used to produce weird occurrences before the altars. However, it is most unlikely that conjurers of the period, in any country, had such close association with the priests as to be told the methods of the temple illusions. It is also doubtful whether the conjurers even knew of the existence of the priestly magic. At any rate, the feats of the ancient conjurers were quite different. The conjurers were able to perform their mysteries anywhere, while, because of the required equipment and preparation, the pagan priests could show their magic only in the temples. Some of the conjurers, however, did turn to their own advantage the superstitious awe in which many held their work.

By the time people were civilized enough to record history, they described the performances of conjurers. These ancient notes are sketchy, but enough is told to know that conjurers' feats were much like those of later periods about which there are more complete reports.

Throughout the entire world, the more skilful of the early conjurers were entertainers at the courts of the rulers, and those of lesser skill performed in the market places for the people or at the feasts of the wealthy. Their feats were very much alike and quite limited in number. The principal trick, which, known as the "Cups and Balls," still is popular, was one in which three inverted cups and a ball were used. The ball mysteriously would jump about invisibly from cup to cup, then multiply into three balls with each seemingly having the ability of undiscernible locomotion. The basis for this mystery is a secret additional ball which, by skilled manipulation, is put under one cup while the known ball is removed, as secretly, from another cup. The manipulative work in this trick, as in most, is aided by the distracting conversation of the conjurer. Because the trick was in the program of every early conjurer, and always a favourite with audiences, magicians received more recognition for the performance of the Cups and Balls than for all their other feats.

The ancient Greek term for conjurer was *Psephopaiques*, and one of the old Roman words was *Calcularius*. Both meant "he who deals with pebbles." In different countries pebbles, or other small objects, were used for the trick instead of balls. The shape and type of cup used also varied. Another Roman word for conjurer, *Acetabularius*, meant, "he who deals with vinegar cups." Descendants of the Roman conjurers used the cylindrical boxwood measures, instead of vinegar cups, and a popular old Italian term for magic was *giuoco di bussolotti*, "the game with the measures." Similarly in France, a conjurer was called *joûeur de gobelets*. A usual adjunct of equipment for the Cups and Balls was a bag, with strings, tied around the waist of the conjurer, like an apron. It was not only a serviceable way to carry the properties of the trick, but was a handy place for the conjurer secretly to acquire or dispose of the balls. Throughout Europe the conjurer's pocket apron was the badge of the profession, and *Taschenspieler*, "pocket player," became the common term for magician in German.

The Cups and Balls is one of the basic tricks of magic, and Egyptian, East Indian, Chinese and other eastern magicians performed the feat exactly as did the Europeans, except, because of the differences in clothing, the pocket apron was never needed by oriental magicians. Other universal tricks of the early conjurers were the restoration of a piece of string which had been severed, and apparently thrusting knives into the body. The first was accomplished by failing to cut the string in the man-

ner suggested, and the second by substituting special, harmless knives for the real ones offered for inspection. Other general used magic was performed with borrowed rings and coins. Another trick done with a borrowed object always has been doubly interesting.

The medieval magicians traveled more than had their predecessors, and, as itinerant mountebank performers, even toured countries other than their own. Their equipment was limited to what could be carried on their backs, and, while the old tricks still were used, the performances were augmented with feats done with borrowed fruit, vegetables and small fowl, as well as with men's hats and women's kerchiefs. With the advent of the printed playing cards, a whole new field of magic was opened, as an infinite number of tricks could be done with cards, and a deck could be carried easily.

More and more, the magicians in their travels followed a regular itinerary and built a following for their annual appearances. Many cities had a "street of the conjurers" where performances could be seen daily. Some magicians were able to give more impressive shows by having extra equipment carried on a donkey or horse, while others joined with entertainers of various other types, ballad singers, storytellers, acrobats and musicians, to give more elaborate performances. These larger shows were given in rented barns or storehouses, and for more people than could see a street or market-place exhibition. The increased remuneration was the magician's greatest interest in the size of his audience.

At least the majority of the feats of the conjurers of old times were recorded. The first book to describe the secrets of sleight of hand and magic equipment was the *Discovrie of Witchcraft* (1584), and it was written by Reginald Scot, who was not a magician, for the sole purpose of convincing the public that sorcery had no part in such performances. The first book devoted solely to the subject, *The Art of Jugling, or Legerdemain* (1614), by S.R. (probably Samuel Rid), and the anonymous last volume *Hocus Pocus Junior* (1634) both gave clearer descriptions of the methods employed in the art. It is likely both volumes were unsigned because their authors feared those who still believed that magicians had contact with devils. Scot's book was burned by the common executioner because of such beliefs. Juggler (from the Latin *joculator*) was an early term for conjurer as was *Hocus Pocus*, used, with other pretended magic words, by performers throughout Europe. These books showed that magicians were learning more about mechanics and how to construct boxes with false bottoms and how to make a bag out of which several liquors could be drawn from the one spigot. A number of books describing the same tricks, written by other magicians, appeared in Europe during the 17th century, though *Engños a Ojos Vistas* (1733), by Pablo Minguet e Yrol, was the only volume to stress the use of the pocket apron. By the 18th century the more advanced and literate conjurers began to write about their work, they not only had discovered better hiding places for the balls but realized that the success of a trick depended more upon the acting ability and manner of the performer than on any piece of equipment.

**Beginning of Stage Performances.**—In the 18th century many more books on magic appeared, but the only advance recorded of the art was the use of magical automata and apparatus. The transference of thought from a magician to his assistant. The latter was first shown (1781) by Philip Breslaw (1726-1803) and later (1783) by Giuseppe Pinetti de Wildalle (1750-1800). Occasionally, magicians exhibited true automata (i.e., motions entirely by mechanics), though usually their figures were pseudo-mechanical masks for the tricks performed. While such automata as a doll which would play on a flute any tune requested or a bird which would blow out the flame of one candle and light another by a further gust were tricks, not mechanics, they added interest and variety to the performances. Real automata figures were publicly exhibited, usually by the mechanics who made them and were interesting to the public because of their ingenious construction. Magical automata did what was impossible for the mechanical kind.

The great increase in equipment made necessary semipermanent quarters, with stages better suited to display the tricks, so conjurers rented stores and halls and made them into small theatres. The portability of equipment no longer being the first consideration, magicians started using large and completely draped tables with trap doors operated by hidden assistants. An object placed on such a table and momentarily covered from the sight of the audience could be caused to disappear or to become totally different by the mere command of the magician, plus the work of the hidden assistant. Because of the quantities of apparatus, magicians avowed supermechanical knowledge and based their wonders on a scientific claim rather than the magic words previously used.

The public did not object, for people were becoming conscious of the remarkable possibilities of mechanics and were losing interest in the pretense of magic spells. Professor as a title for magician, invariably self-bestowed, became generally accepted. Many traveling conjurers also were using more equipment which was transported in special wagons. The rear of such a wagon would open to form a stage; the front would make the living quarters. In short, the wagon was both a home and a stage on wheels.

Of course, some magicians continued to perform in market places, at fairs and in barns and taverns, but changes were occurring in magic. Notable conjurers of this period were: Isaac Fawkes (1675?-1731), Christopher Pinchbeck (1670-1732), Jacob Meyer (1735-90), who was known as Philadelphia, Kalterfelto (1730?-99), Flockton (1740?-94) and Lane, about whom there is little personal data.

Possibly greater public interest in magicians and their work than previously had been given was accorded performers of the 18th century because they advertised themselves in newspapers and further attracted personal attention by wearing striking costumes at all times. Though certain conjurers added ventriloquism, juggling, sword swallowing or even fire eating and other "heat-resistant" feats to their magic exhibitions, such demonstrations were no more a part of conjuring than was medicine because some conjurers sold curatives in connection with their shows.

Once magicians had theatres to play in, and could use quantities of equipment, their shows became extremely elaborate and, in the early 19th century, stages were filled with apparatus frequently claimed to be constructed of solid silver. Only a part of the equipment was employed in any one performance, and some of the most ornate pieces had no use other than to add to the number of articles displayed. The printed programs carried long lists of the names of tricks possessed by the magician from which a selection was supposedly made for each entertainment. While many of the tricks were performed by all the magicians, new program names for the tricks were devised by each one. The elaborate paraphernalia-decked stages and the costly and fanciful costumes assumed by the magicians lent a grandeur to the performances that earlier shows had lacked. The greatest conjurers of this type were: Bartolomeo Bosco (1790-1863), Ludwig Leopold Döbler (1801-64), Philippe (Jacques Noel Talon, 1802-78) and Alexander (Johann Frederick Alexander Heimbürger, 1819-1909). All were great travelers who gave their shows in many countries.

One of the last of these great ornamental conjurers was Dunkell (Henri Robin, 1805-74), a native of the Netherlands, who pretended to be French. He claimed to be the inventor and was, at least, the first to show (1847) the illusion later known as "Pepper's Ghost." It was based on an optical principle Baptista Porta, the Italian philosopher, had described in effect 300 years earlier (*Magia Naturalis*, 1588), by which, on an inclined plate glass, a transparent reflection, or ghost, could be made of a person hidden to the audience. The ghostly effect was enhanced because the spectre, on the unseen glass, seemed to walk about among living people. These actors were behind the glass and had rehearsed their parts carefully so that their actions coincided with those of the actor, who, in a different part of the theatre, was the original of the ghost. The illusion depended largely upon the arrangement of the lights, which could be controlled to give

any amount of substantiability to the ghost or cause it to disappear altogether.

For the few years until the public learned of the method employed, the ghost illusion had great popularity. Its importance to the history of conjuring is that it was the first of the tricks utilizing glass. Later conjurers made full use of sheet glass, both plain and silvered, in designing magical illusions. Spectres, having little or no action and lacking the ability to mingle with humans, had been produced earlier by means of magic lanterns. This method to produce ghosts had been mentioned, in a vague way, by writers long before the magic lantern's accredited invention by Athanasius Kircher in the 17th century. While such lanterns probably had long been used by charlatans to bring forth ghosts and demons, there is no evidence of their use for entertainment by conjurers until 1784 in a show produced by Robertson (Etienne Gaspard Robert, 1763-1837), a Belgian optician and magician, even though they had been described most inadequately since 1727 in books on magic.

**Beginning of Modern Magic.**—In contrast to the elaborately equipped, fantastically dressed school of conjurers, another group went to the opposite extreme. Actually Conus (sometimes called Comus, and whose real name was Cotte; d. 1836) was the forerunner of the advocates of simplicity of performance, though Wiljalba Frikell (1818-1903) was the real leader. Frikell was the first magician to appear in conventional evening clothes. His magic depended almost entirely upon his personal skill, and he eschewed most of the usual equipment. He wrote (*Lessons in Magic*, 1858) that "the use of complicated and cumbrous apparatus diminishes the amount of astonishment conjurers are enabled to produce which is a defect not compensated by the external splendor and imposing effect of such paraphernalia." Johann Nepomuk Hofzinsler (1806-75), an Austrian, who appeared only in his own country, was among the other conjurers to eliminate displays of apparatus from their shows. These simplified exhibitions required new tricks, and Hofzinsler devised many varied feats of magic and was the most prolific inventor of card tricks. Although comparatively few magicians went to the extreme of Frikell and Hofzinsler, their work had an enormous effect on the shows of all later conjurers.

John Henry Anderson (1812-74), a Scot, who called himself the Great Wizard of the North, while considerably influenced by advocates of simplification in later life, was in another field a leader of magicians. Anderson was the first great advertiser and, by example, showed that tremendous public interest could be invoked in exhibitions of magic, particularly when the interest first was directed toward the performer himself. The people showed their countenance of Anderson and his magic by paid attendance at his shows.

Robert-Houdin (Jean Eugene Robert, 1805-71), a Frenchman, made so many improvements in magic equipment and so carefully and systematically classified all that was known about presentation that he is called the father of modern conjuring. While he claimed to have originated almost all the tricks he performed, as well as the innovations in performance, actually his work was based largely on the best ideas of his predecessors. Robert-Houdin followed Frikell in adopting gentlemen's attire, and though he did not do away with apparatus, he did, in the main, use what appeared to be common and familiar objects. He modernized the mechanical marvels originated by Pinchbeck and others and improved the table mechanisms which Pinetti had devised, to eliminate the necessity for draped tables with hidden assistants. Pinetti had used tables with tops which, while no thicker than normal tables, concealed levers with cords running to off-stage assistants by which to operate mechanical tricks placed on the tables.

Robert-Houdin ran electric wires to his tables which operated electromagnets instead of levers, as well as cords, motivating pistons. He was the first, and one of the very few magicians, ever to utilize electromagnetism, though Döbler previously had used electricity in his feat of causing 200 candles to light simultaneously upon the firing of a pistol, and Philip Breslaw had used a common magnet to control the activities, on the surface of water

in a bowl, of "The Learned Swan," a wooden figure with an iron core.

In 1849 Robert-Houdin made a sensation with his floating boy. It was a marked improvement on a mysterious suspension which, in 1826, Ling Lau Lauro had been the first to show in the occident, although there are records of its having been shown several years earlier in Madras, India, and possibly was of Indian invention. In the original effect, a person sat cross-legged, several feet in the air, upon nothing. The fingers of the floating man's one outstretched arm lightly touched a perpendicular bamboo rod set upon a stool or platform raised above the stage. The secret was that inside the bamboo pole, affixed to the platform, ran an iron bar bent at the top at right angles and to which was attached a metal support to uphold the body. The body support, and such of the iron outside the bamboo pole, was covered by the sleeve and clothing of the subject, and, necessarily, screens or curtains had to mask the preparation for suspension. Robert-Houdin made a metal body rest which could be worn inside the subject's clothing and had a mechanical method by which the support and the pole could be connected, in full sight of the audience, to allow the boy to lie horizontally in the air. He added to the presentation by giving an acceptable, though false, reason for the suspension. It was claimed to be the effects of ether, which had the property of making a body totally devoid of weight. Ether was then a new discovery, and its real qualities were known only to a few scientists. Robert-Houdin also materially improved the signaling method for apparent "thought transference," which had been a feature of Pinetti and others. Many of Robert-Houdin's "inventions" may be shown to be of earlier origin, but he brought each to a point of perfection undreamed of by the originators. Robert-Houdin influenced a number of magicians, including Anderson, and was copied slavishly by Robert Heller (William Henry Palmer, 1830-78) and others. Heller, an Englishman, even went to the length of dyeing his hair and assuming a French accent in his attempt to be like the other man. Heller's success waited upon resumption of his own personality, his brilliantly witty style of performance, and in following Robert-Houdin only in ideas. Georges Méliès (1861-1938), who had been a student of Robert-Houdin and was later the proprietor of the Théâtre Robert-Houdin in Paris, became interested at the end of the 19th century in the newly invented motion-picture camera and its possibilities as a vehicle for conjuring. The Méliès magic films, if viewed by an audience sophisticated in the modern techniques of motion-picture photography, would seem obviously deceptive, but they were sensations in 1900. In his attempts to mystify the viewers of his films, Méliès evolved such currently accepted camera practices as the fade-out, the lap dissolve and the double exposure.

Robert-Houdin led also in writing professional books on magic. Prior to his works there had been but one real manual on the subject, *La Sorcellerie Ancienne et Moderne Expliquée, ou Cours Complet de Prestidigitation* (1853), by Jean Nickolas Ponsin (1777-1853), a French amateur. All the earlier publications, including Henri Decremps (1746-1826?), *La Magie Blanche Dévoilée* (1784) and later works, while tremendously interesting as historical records, merely exposed, with little detail, the methods by which tricks were done and contained nothing on how to learn to do them. While Ponsin actually described how to do tricks, Robert-Houdin, possibly because of his greater knowledge of the subject, gave an understanding of the underlying art of magic, as well as superb lessons, in *Les Secrets de la Prestidigitation et de la Magie* (1868). Robert-Houdin's other books also are excellent, and all have been translated into several languages. Following Robert-Houdin, hundreds of other magicians have contributed, in many languages, to the literature of the subject. A large proportion of the books on the art are privately circulated professional publications.

Two of the best-known conjurers were Compars (Carl) Herrmann (1816-87) and his younger brother Alexander (1843-96), known as Herrmann the Great. They used comparatively little equipment and were most skilled manipulators, though, in later life Alexander performed a number of large illusions which had come into vogue. Other prominent performers of the period

were: Signor Antonio Blitz (1810-77), Joseph Michael Heller (1836-1903), Louis Haselmayer (1839-85), Baron Hartwig Seeman (1833-86), Le Commandeur Bernard Marius Cazenove (1839-1913), The Fakir of Oolu (Alfred Sylvester, 1831-86), J. Lynn (Hugh Simmons, 1838?-96) and Colonel Stodare (Jean English, 1831-66). Through their constant travels they gathered the magic of the entire world and added it to their shows, and all invented some magic. The Fakir of Oolu devised an improvement on the suspension, which permitted the floating person to be shown in several changes of position and permitted also the final removal of the supporting rod. The rod was removed in a dim light and was accomplished by having a shell stage which could be taken off the iron rod. The iron rod was covered with dull material matching the back curtain and became invisible in dim light.

Hartz and Stodare invented many small tricks which remain popular. Stodare, with an illusion the "Sphinx," invented by Thomas William Tobin of the Polytechnic institution, was the first magician to make use of mirrors to hide objects. The effect of the illusion was that a live (though bodiless) head of a man rested on a light three-legged table in the centre of the stage. The secret was that between the legs of the table were mirrors set at proper angles to reflect the sides of the stage which had hanging identical with those behind the table. The spectators appeared to be able to see the back curtain through the legs of the table, though actually they saw the reflections of the side curtains. The mirrors were invisible because the edges were masked by the table legs. Behind the mirrors was ample space for the body of the man who, through a hole in the table top, exhibited his "attached" head.

**Modern Magic.**—John Nevil Maskelyne (1839-1917) played an enormous part in the advancement of magic. He invented a number of magical effects; he founded a theatre of magic in London, which he, his sons and grandsons ran for over 50 years. He encouraged, engaged in and advised with the inventions of scores of other magicians. He originated (1865) the feat of escape from a box which was locked and roped after he had entered. He caused a levitated person to rise and fall in the air (1875), and was the first to eliminate all visible means of support. His son Nevil Maskelyne (1863-1924) added the use of a large solid box to pass over the floating lady, a convincing way of showing the absence of support. Again, in "Cleopatra's Needle" (1875) Maskelyne was the first to use the counterweight principle to make a heavy object void of weight. In this illusion, an oblong shaped box was carried about the stage as if it were extremely light, though two persons, who later appeared, were hidden inside all the time. Maskelyne also constructed the two best magical automaton figures: "Psycho" (1875) was a card player and calculator built on an idea of John Algernon Clarke, and "Zoe" (1877) was a portrait artist who drew likenesses of famous celebrities.

For many years, Maskelyne had George A. Cooke as a business associate, and the names of Maskelyne and Cooke became synonymous with conjuring. After Cooke's death (1904), Maskelyne took David Devant (David Wighton, 1868-1941) into a partnership, which lasted until 1915. Devant, the greatest of English conjurers, was prolific with new ideas in magic. Buatier de Kolta (Joseph Buatier, 1845-1903), who appeared in many of Maskelyne's shows, invented some of the most striking ever performed. His "Vanishing Lady" (1886) and the "Bird Cage" (1873) were the best of his many inventions. Devant depended more upon the manner of performance than on the equipment used. De Kolta also improved "Black Art," or "Modern Black Magic," a series of effects first shown by Max Anderson (1839-1928), who usually performed under the name of Ben-Bey. Black art is based on the optical principle that, with proper lighting conditions, both shadow and form can be eliminated. Objects will seem to be invisible when covered with light-absorbing material (usually black, hence the name), identical with the background. Using this principle, anything can be caused to disappear upon being covered with cloth, or be made to appear by reversing the operation. Assistants, handling the covers, were themselves

"invisible" because of the material of their completely enveloping costumes.

Harry Kellar (1849–1922), the first great American-born magician, made many refinements in magic and performed superbly the large as well as the small tricks. Beginning with the final decade of the 19th century, American magicians were the first to specialize in their magic. Among these specialists were: Howard Thurston (1869–1936), who originally performed only with cards; Thomas Nelson Downs (1867–1938), who did magic only with coins; and Harry Houdini (*q.v.*), who exhibited feats of extrication from ropes, handcuffs and shackles. These conjurers had, of necessity, to originate a large proportion of their tricks and, particularly in modes of manipulation, added materially to methods in magic. Thurston later took over the Kellar show, and Houdini also added diverse magic to his performances. Other specialists were Horace Goldin (1873–1939), who featured large effects shown with extreme rapidity, and Nate Leipzig (1837–1939), who did only small tricks requiring great dexterity. Goldin invented many famous illusions, among which was "Sawing a Woman in Half" with a motor-driven circular saw.

Magicians strive constantly to add new material to their shows, but not all possess inventive abilities. Some of those who devise the best magic are not good showmen, and the public will remember the tricks of a great performer rather than the original magic of one less skilled in presentation. For example, the performances of the Great Lafayette (Siegmund Neuberger, 1872–1911) or those of Chung Ling Soo (William Ellsworth Campbell, 1861–1918), who styled his stage name after the great Chinese magician Ching Ling Foo (Chee Ling Qua, 1854–1918), advanced magic and the professional status of magicians more than did the inventions of Selbit (Percy Tibbles; *d.* 1938), one of the most original magicians. The successful magician's showmanship is based on his ability to play a role and whether he appears to be a "professor," a "sorcerer" or a "charming young man" his effective performance will play a larger part in winning his audience than will his magical invention.

Two major factors have caused magicians to simplify their equipment and to develop a more intimate manner of presentation in the years after 1930. The first of these is the extinction, due largely to economic factors, of the touring magic show which constituted a full evening's entertainment—a type of presentation associated with Kellar, Thurston and, in its last days, Harry Blackstone and Dante. The second factor lies in the tremendous advances in science together with the everyday use of its applications and developments. It is manifestly difficult to impress an audience which receives moving images in its homes via television with the magic of a mirror trick or a phantasm thrown by a hidden projector on a puff of smoke.

Magicians of today, therefore, attempt to appear less like sorcerers or "professors" and more like attractive and extremely skillful actors, and their equipment is made to look as ordinary and unmagical as possible. The main arena of performance for the magician is in the night club, where his act must be on and off stage quickly and short and compelling enough to compete with the attractions and distractions which abound. Occasional attempts to televise magic have proved largely unacceptable to audiences which distrust the possibility that the tricks are achieved by camera sorcery. Conjuring may be fully effective only in "live" performance.

For magic in primitive cultures, see **MAGIC**.

**CONKLIN, EDWIN GRANT** (1863–1952), U.S. biologist noted for his studies of human evolution, was born at Waldo, O., on Nov. 24, 1863. He graduated at Ohio Wesleyan university,

Delaware, O., in 1886 and received from Johns Hopkins university, Baltimore, Md., in 1891 the degree of Ph.D. He was professor of biology at Ohio Wesleyan in 1891–93, and professor of zoology at Northwestern university, Evanston, Ill., from 1894 to 1896 and at the University of Pennsylvania, Philadelphia, from 1896 to 1904 when he was appointed to a similar chair in Princeton university. He made valuable researches in embryology and cytology and in the mechanism of heredity and evolution, and by his skill as an investigator, teacher and writer rose to foremost rank among American zoologists. Besides numerous contributions to scientific journals, his writings include *Heredity and Environment in the Development of Men* (1915–21), *Direction of Human Evolution* (1921) and *Problems of Organic Adaptation* (1921). He retired from active teaching in 1933 and spent the years thereafter in research. He died Nov. 20, 1952.

**CONKLING, ROSCOE** (1829–1888), a prominent U.S. lawyer and influential Republican member of congress during the Reconstruction era. He was born at Albany, N.Y., Oct. 30, 1829, the son of Alfred Conkling (1789–1874), a distinguished jurist, legislator and diplomat. Obviously destined for politics, Roscoe Conkling made his first campaign speeches in 1848 in behalf of Zachary Taylor and Millard Fillmore. After studying law in Utica, he was admitted to the bar in 1850. Between 1850 and 1858, he won an enviable reputation as an orator, lawyer and political leader. Conkling was a keen debater and possessed a striking personality. As a Whig he took part in the campaign of 1852 in behalf of Gen. Winfield Scott. He was active in the formation of the Republican party and helped the party carry New York state for John C. Frémont in 1856. He was elected to the U.S. house of representatives in 1858 and again in 1860. He was defeated for re-election in 1862 by Francis Kernan, but in turn defeated Kernan in 1864.

Conkling upheld the Lincoln administration in its conduct of the Civil War but consistently attacked the generalship of Gen. George B. McClellan. Conkling was chairman of the committee on the District of Columbia; member of the special joint reconstruction committee of fifteen; and of the ways and means committee. He was an avid supporter of the 14th amendment to the constitution. He was re-elected in 1866 but did not take his seat because he was elected to the senate in Jan. 1867. Conkling was re-elected in 1873 and 1879. As a senator he early showed his aptitude for leadership. He was a member of the leading senatorial committees and chairman of the committees on commerce and the revision of the laws. It was his leadership that most influenced the Grant administration in its over-all policy toward the South. He received 93 votes for the nomination for president in the Republican convention of 1876. His support of Grant's nomination for a third term in the 1880 convention caused a split in the Republican party. He and his colleague Thomas C. Platt (*q.v.*) resigned from the senate on May 16, 1881, over a dispute with President Garfield concerning patronage. He sought re-election as a vindication but was defeated. President Arthur, who succeeded to the presidency after Garfield's assassination, offered Conkling a seat on the bench of the U.S. supreme court in 1882 but he refused the appointment. He then practised law in New York city where he died on April 18, 1888.

See D. B. Chidsey, *Gentleman from New York: a Life of Roscoe Conkling* (1935). (F. M.)

**CONN** (fl. 2nd century A.D.), Conn Cétchathach, "Conn of the Hundred Battles," is, in the heroic tales, one of the most famous of Irish kings. T. F. O'Rahilly in his *Early Irish History and Mythology* (1946) raises or reduces him to the status of a god of the other world, but this view is very difficult to accept. Variants of the name, such as Condos, Senocondos, Condollus, are found attached to very ordinary mortals among the Celts of Gaul and the epithet "of the Hundred Battles" suggests vigorous human activity. More important still as evidence of his existence and his prowess is the term Leth Cuinn ("Conn's Half") applied to the northern half of Ireland in which Conn held sway. The earliest recorded political division of the country is into five parts: Ulster, Tara (Meath), Leinster, Munster and Connaught. By the 5th century there had come into being the title "king of Ire-

land," thereafter long held alternately by members of two branches of the royal line descended from Conn, established respectively in the midlands and in the north. The term "Conn's Half" most probably came into use during an intermediate stage in the process of unification, when Conn was predominant in the northern half of Ireland but could not win even nominal allegiance from the southern half, then known as Leth Moga Nuadat or Leth Moga ("Mog's Half") after the Eoganachta king Eogan, or Mog Nuadat, who ruled there. All the stories of Conn in Irish literature are in the traditional style, full of romance with a kernel here and there of history. In the genealogies Conn is the ancestor of Niall of the Nine Hostages (379–405) and through him of the greatest dynasty known to Irish history, the Uí Néill.

(J. J. Ry.)

**CONN (CON), LOUGH**, a lake in County Mayo, western Ireland, is drained through the river Moy into Killala bay. At Pontoon, Lough Conn is joined to the smaller Lough Cullin (3 sq.mi.) to form a fine sheet of water 11 mi. long and 4 mi. wide. Lough Conn is floored by Carboniferous limestone and, standing at 42 ft. above sea level, is essentially a lake of the lowland. The limestones give place to older rocks, locally granites, which extend westward to the Atlantic shores. A short distance to the west, Nephin (2,646 ft.) and other mountains rise to more than 2,500 ft. The shores are varied and in places consist of peat bogs but in others of closely formed ridges of glacial drift. There are numerous islands in the lakes, none of them inhabited. There are no villages on the lake shores and many of the farms are remote and can be approached only by rough lanes. At Pontoon the bridge across the channel connecting the two loughs is a favourite angling spot, and in this area there are some fine woods, believed to be the native forest, of oak, or oak with birch, varied with rowan, holly, ash, hazel and a rich ground vegetation.

(T. W. Fr.)

**CONNAUGHT, ARTHUR WILLIAM PATRICK ALBERT, DUKE OF** (1850–1942), third and favourite son of Queen Victoria, was born at Buckingham palace on May 1, 1850. He was created duke of Connaught and Strathearn in 1874. He entered the Royal Military academy, Woolwich, in 1866 and did well in the army, becoming full general in 1893 and field marshal in 1902. He served in Egypt in 1882, commanding the guards brigade at Tel el Kebir. He then went to India and held the Bombay command from 1886 to 1890. Returning to England, the duke held various military appointments, notably commander in chief in Ireland (1900–04), inspector general to the forces (1904–07) and commander in chief in the Mediterranean (1907–09). As governor general of Canada (1911–16) he was very popular but his governorship was not without controversy, largely resulting from his attempt to intervene in Canadian military affairs. Connaught's state functions included the opening of the first parliament of the Union of South Africa in 1910 and the inauguration of the new chamber of princes, legislative assembly and council of state in India in 1921. He withdrew from public life in 1928 and died at Bagshot park, Surrey, on Jan. 16, 1942.

In 1879 the duke had married Princess Louise Marguerite of Prussia (d. 1917). Their elder daughter, Margaret (1882–1920), married the crown prince of Sweden (later King Gustavus VI) in 1905. The duke's only son, Prince Arthur of Connaught (1883–1938), married, in 1913, Princess Alexandra, duchess of Fife (1891–1959). Their son Alastair Arthur (1914–43) succeeded his grandfather in 1942, but on his death in 1943 the dukedoms became extinct.

**CONNAUGHT (CONNACHT)**, one of the five ancient kingdoms or provinces of Ireland, lies in the western and northwestern areas of the island. Its eastern boundary is still, in large part, the middle course of the river Shannon. It comprises the counties of Mayo, Sligo, Leitrim, Galway and Roscommon (qq.v.). Area 6,611 sq.mi.; pop. (1961) 419,465.

In early times Connaught (Cóiced Connacht) was divided into three regions, from north to south, Gamanraige, Tuatha Taiden and Fir Craibe. About A.D. 400 the kingdom lost to Munster that part of Fir Craibe which is now the county of Clare. Meanwhile, in the 4th century, the great Irish rulers of the midlands, whose

central fortress was Tara, had displaced the ancient line of Connacht kings and a close connection began between Tara and Crúachu (Rathcroghan, County Roscommon), the traditional capital of the Connacht state. To this Tara dynasty belonged Bríón and Fiachra, who in the 5th century founded septs, Uí Briúin and Uí Fiachrach, that were to give the kingdom all its name until the Norman invasion.

Toirdelbach (Turloch) O'Connor (d. 1156) was strong enough to claim the kingship of Ireland, and his son Ruadri (Rory) was generally recognized as king of Ireland when the Norman knights and later Henry II himself came to deprive him of that position (1171). But Ruadri's brother Cathal Crobberg ("of the Red Hand") O'Connor was king of Connacht to his death in 1210. Henry III then made a grant of the kingdom in 1227 to Richard de Burgh and Richard's son Walter became earl of Ulster (1244) as well as lord of Connaught. When William de Burgh, earl of Ulster, was murdered in 1333, he left no male heir; his daughter married Lionel, afterward duke of Clarence, and the title was subsequently transmitted through their daughter Philippa to the Mortimer earls of March and ultimately to the crown (1400). Connaught was, however, occupied by junior branches of the de Burghs, who took respectively the appellations of MacWilliam Uachtar and Iochtar ("the Upper and Lower MacWilliam") and became the Clanricarde and Mayo Burkes. In 1543 Ulick de Burgh was created earl of Clanricarde and in 1603 MacWilliam Iochtar, Viscount Mayo.

In 1576 Connaught was divided into shires by the lord deputy Sir Henry Sidney, who had also placed it, like Munster, under a president (1569), a system which remained effective for about 70 years and was not finally abandoned until 1662. In 1585 St. John Perrot made with the resident gentry and chiefs the "composition of Connaught," which confirmed to them possession of their lands by knight service of the crown. The result was that most of the province remained loyal to the crown during the Tyrone rising (1594–1603) and remained the most Gaelic of the Norman part of Ireland. For its subsequent history see *Ireland History*.

(J. J. Ry.)

**CONNECTICUT**, one of the 13 original states of the union and one of the New England group, is bounded north by Massachusetts, east by Rhode Island, south by Long Island sound and west by New York; the southwest corner projects along the sound indenting New York for about 13 mi. It is the 48th state in area, Rhode Island and Delaware being the only states smaller in area. The state capital is Hartford and the state ratified the constitution Jan. 9, 1788. The white oak has been designated the state's official tree, the mountain laurel its official flower and the robin the official bird. The state flag is composed of a white shield on a blue background. Beneath the shield is a white streamer bearing the state motto (*Qui transtulit sustinet*, "He who transplanted sustains"). "Connecticut" is supposed to mean "beside the long tidal river" and is of Indian origin. It is called the "Nutmeg state," from the notion that, in the early days, its residents were so shrewd they could sell wooden nutmegs.

The state has 169 towns (many of which are townshiplike in character) which are the principal units of local government.

### PHYSICAL GEOGRAPHY

**Physical Features.**—Connecticut lies in the south portion of the peneplain region of New England, between approximately 40° 00' and 42° 03' N. and 71° 47' and 73° 40' W., and its total area is 5,009 sq.mi., of which 110 are water surface. Its surface is generally that of a gently undulating upland divided near the middle by the lowland of the Connecticut valley, the most striking physiographic feature of the state. The upland rises from the low south shore of the state at an average rate of about 20 ft. a mile until it has a mean elevation along the north border of 1,000 ft. or more, and a few points in the northwest rise to a height of about 2,000 ft. above the sea. The lowland rises slowly from under the waters of Long Island sound in the south to a height of only 100 ft. above them where it crosses the north border. In the north the lowland is about 20 mi. wide: in the south it narrows to only 5 mi.; its total area is about 1,400 sq.mi. Its formation

caused by the removal of a band of weak rocks by erosion after the general upland surface had been first formed near sea level and then elevated and tilted gently south or southeast; in this band of weak rocks were several sheets of hard igneous rock inclined from the horizontal several degrees and so resistant that they were not removed but remained to form ridges, such as West Rock ridge near New Haven and the Hanging hills of Meriden. The ridges are generally deeply notched, but their highest points rise to the upland heights directly to the east or west. The west section of the upland is more broken than the east section, for in the west are several isolated peaks lying in line with the south continuation of the Green and the Housatonic mountain ranges of Vermont and Massachusetts, highest among them being: Bear mountain 2,322 ft.; Gridley mountain, 2,211 ft.; Mt. Riga, 2,010 ft.; Mt. Ball (Bald), 1,770 ft.; Lions Head, 1,738 ft.; Canaan mountain, 1,762 ft.; and Ivy mountain (Goshen), 1,658 ft. The lowland is drained by the Connecticut river as far south as Middletown, but there the river turns to the southeast into one of the narrow valleys in the east section of the upland, the turn being caused by the fact that the river acquired its present course when the land was at a lower level and before the lowland on the soft rocks was excavated. The principal rivers in the west section of the upland are the Housatonic and its tributary, the Naugatuck; in the east section is the Thames, which is really an outlet for three other rivers (the Yantic, the Shetucket and the Quinebaug). The Connecticut river is navigable as far as Hartford, and the Thames as far as Norwich. The Housatonic river, which traverses the whole breadth of the state, has a short stretch of tidewater navigation. The seacoast, about 100 mi. in length (not recognizing coastal indentations), has a number of bays, making several good harbours which have been created by a depression of small valleys.

In spite of the fact that Connecticut is a highly urbanized state, approximately 60% of its landscape is forested. There are 26 state forests, the largest of which are Tunxis (in Hartland), Pachaug (Voluntown), Natchaug (Eastford), Housatonic (Sharon), Cockoponsett (Chester) and Nipmuck (Union). In addition there are nearly 600 state and local parks. The acreage of cultivated farm land has been declining for more than a century.

**Climate.**—The climate of Connecticut, though temperate, is subject to sudden changes; yet the extremes of cold and heat are less than in the other New England states. The mean annual temperature is 49° F., the average temperature of winter being 27° and that of summer 72°. Since the general direction of the winter winds is from the northwest, the extreme of cold is felt in the northwestern part of the state. The prevailing summer winds, which are from the southwest, temper the heat of summer in the coast region, but extreme heat is found in the central part of the state. The annual rainfall varies from 45 to 50 in.

**Vegetation and Animal Life.**—Mountain laurel, the state's official flower, grows profusely on the rocky Connecticut hillsides. Some towns have laurel festivals in the spring. Almost as common as laurel are white dogwood and pink azalea, the latter known locally as honeysuckle. Among the wild flowers frequently seen in Connecticut's woods are trailing arbutus, violets, hepatica, blood-root, jack-in-the-pulpit, cowslips, buttercups, wild geraniums and lupine. The trees are largely hardwood with oak, ash, birch, hickory, poplar, sycamore, beech, hard maple and butternut the most common. In the northern part of the state hemlock and white pine are abundant. Other typical Connecticut trees are sugar maple, red pine, black walnut, elm and willow.

Small animals common in the state include foxes, rabbits, squirrels, woodchucks and skunks. White-tailed deer may be seen, and mink, muskrat and otter are sometimes trapped. Of the kinds of birds most often seen, some of the commonest are clapper rails, fish crows, orchard orioles, hooded warblers, brown creepers, water thrushes, juncos, sapsuckers and robins. Game birds include freshwater ducks, ruffed grouse, quails and pheasants.

**State Parks and Historic Sites.**—Connecticut has set aside an unusually large proportion of its total land area for public parks and forests. New Britain ranks second among all the cities in the United States in the amount of its area in public parks, per unit of population. There are more than 70 state parks which total

about 21,000 ac.; there are 26 state forests covering approximately 122,000 ac. The latter are designed to preserve and develop the forest for the enjoyment of future generations, but they are also open for hiking, hunting and other outdoor activities.

State monuments include an old iron furnace at North Caanan; the Israel Putnam burial place at Brooklyn; the John Mason burial place at Groton; the place Indian Chief Miantonomo died at Norwich; the burial place of Nathan Hale at Coventry; the burial place of Nathaniel Lyon at Eastford; a site of a fort at Old Saybrook; and the site of an Indian battle at Fairfield.

Among the more outstanding buildings of historic interest are the Trumbull house (1740), the home of Revolutionary War Gov. Jonathan Trumbull at Lebanon; the Nathan Hale homestead (1776) at South Coventry; the first law school (Tapping Reeve) in the United States, established in 1784, at Litchfield; the old state house (1792-95) designed by Charles Bulfinch, at Hartford; and what is probably the oldest stone house in the U.S., the Henry Whitfield house at Guilford, built in 1639 and now a museum. Other notable houses are the Samuel Huntington house at Norwich; Glebe house at Woodbury; the Oliver Ellsworth house at Windsor; Gay manse at Suffield; Lyons house at Greenwich; Grave house at Madison; Whitman house at Farmington; the Silas Deane house at Wethersfield. The Wadsworth athenaeum and the Mark Twain memorial (the writer's one-time home) are at Hartford. The Mystic Seaport and Marine museum at Mystic houses an outstanding collection of clipper ship models. The annual Shakespeare festival at Stratford is also of considerable interest.

Only a few of the historical sites found in the state are associated with American wars. Of these the principal one is Ft. Griswold in Groton, the site of a skirmish in the Revolutionary War.

A characteristic feature of the Connecticut landscape is the village green surrounded by white, frame, colonial houses. Many of the towns are well preserved, notably Guilford, Wethersfield, Farmington, Woodstock, Litchfield, Hampton, Chaplin, Old Lyme and Lebanon.

## HISTORY

**Colonial Period.**—The first settlement by Europeans in Connecticut was made on the site of the present Hartford in 1633 by a party of Dutch from New Netherland. In the same year a trading post was established on the Connecticut river, near Windsor, by members of the Plymouth colony, and John Oldham (1600-36) of Massachusetts explored the valley and made a good report of its resources. Encouraged by Oldham's account of the country, the inhabitants of three Massachusetts towns, Dorchester, Watertown and New Towne (now Cambridge), left the colony for the Connecticut valley. The emigrants from Watertown founded Wethersfield, the first English settlement in Connecticut, in the winter of 1634-35; those from Dorchester settled at Windsor in the summer of 1635; and in the autumn of the same year people from New Towne settled at Hartford. This removal to Connecticut, in which they were led principally by Thomas Hooker (*q.v.*), Roger Ludlow (*c.* 1590-1665) and John Haynes (*d.* 1654), was caused by the colonists' discontent with the autocratic character of the government in Massachusetts. However, the instrument of government which they adopted in 1639, known as the Fundamental Orders of Connecticut, reveals no radical departure from the institutions of Massachusetts. Their most original feature was the omission of a religious test for citizenship. On the other hand, the union of church and state was presumed in the preamble, and in 1659 a property qualification (the possession of an estate of £30) for suffrage was imposed by the general court.

Another migration to the Connecticut country began in 1638, when a party of Puritans who had arrived in Massachusetts the preceding year sailed from Boston for the Connecticut coast, and there founded New Haven. Soon after their arrival these colonists drew up a "Plantation covenant" which made the Scripture the supreme guide in civil as well as religious affairs; but no copy of this is now extant.

A third Puritan settlement, named Saybrook, was established in 1635 at the mouth of the Connecticut river, under the auspices of an English company. Immigration from England soon de-

clined because of the Puritan revolution, and the colony was sold to Connecticut in 1644.

**Unification.**—The next step in the formation of modern Connecticut was the union of the New Haven colony with the older colony. This was accomplished by the royal charter of 1662, which defined the boundaries of Connecticut as extending from Massachusetts south to the seas and from Narragansett bay west to the South seas (Pacific ocean). This charter had been secured without the knowledge or consent of the New Haven colonists, and they naturally protested against the union with Connecticut. But because of the threatened absorption of a part of the Connecticut territory by the colony of New York, granted to the duke of York in 1664, and the news that a commission had been appointed in England to settle intercolonial disputes, they finally assented to the union in 1665. Hartford then became the capital of the united colonies, but shared that honour with New Haven from 1701 until 1875. The 1662 charter created a corporation under the name of the Governor and Company of the English Colony of Connecticut in New England in America, sanctioned the system of government already existing, provided that all acts of the general court should be valid upon being issued under the seal of the colony, and made no reservation of royal or parliamentary control over legislation or the administration of justice. Consequently there developed an independent, self-reliant colonial government which looked to its chartered privileges as the supreme source of authority.

**The Charter Oak.**—The period of most serious friction in the early life of Connecticut was that during the administration of the New England colonies by Sir Edmund Andros (*q.v.*), who in pursuance of the crown's policy both in England and in its American colonies visited Hartford on Oct. 31, 1687, to execute quo warranto proceedings against the charter of 1662. It is said that in the course of a discussion at night over the surrender of the charter the candles were extinguished, and the document itself (which had been brought to the meeting) was removed from the table where it had been placed. According to tradition it was hidden in a large oak tree, afterward known as the "Charter Oak." But though Andros thus failed to secure the charter, he dissolved the existing government. After the English Civil War of 1689, however, government under the charter was resumed, and the crown lawyers decided that the charter had not been invalidated by the quo warranto proceedings.

Religious affairs formed one of the most important problems in the life of the colony. The established ecclesiastical system was the Congregational. The code of 1650 (Connecticut) taxed all persons for its support, provided for the collection of church taxes by civil distraint if necessary and forbade the formation of new churches without the consent of the general court. The new Half-way covenant of 1657, which extended church membership so as to include all baptized persons, was sanctioned by the general court in 1664. Throughout most of the 18th century there was constant friction between the establishment and the nonconforming churches; but in 1791 the right of free incorporation was granted to all sects.

**The Revolutionary Period.**—Connecticut took a prominent part in the American Revolution. At the time of the controversy over the Stamp act the general court instructed the colony's agent in London to insist on "the exclusive right of the colonists to tax themselves, and on the privilege of trial by jury," as rights that could not be surrendered. The patriot sentiment was so strong that loyalists from other colonies were sent to Connecticut, where it was believed they would have no influence, but among the nonconforming sects, on the other hand, there was considerable sympathy for the British cause. Preparations for war were made in 1774; on April 28, 1775, the expedition against Ticonderoga and Crown Point was resolved upon by some of the leading members of the Connecticut assembly; and although they had acted in their private capacity, funds were obtained from the colonial treasury to raise the force which on May 8 was put under the command of Ethan Allen (*q.v.*). More than one-half of George Washington's army at New York in 1776 was composed of Connecticut soldiers. Yet with the exception of isolated British movements against Stonington in 1775, Danbury in 1777, New Haven in 1779 and New

London in 1781, no battles were fought in Connecticut territory.

In 1776 Connecticut was reorganized as a state, the charter of 1662 being adopted by the general court as "the Civil Constitution of this State, under the sole authority of the people thereof, independent of any king or prince whatever." In the formation of the general government the policy of the state was national. It acquiesced in the loss of claimed land in Pennsylvania through a decision (1782) of a court appointed by the confederation; it favoured the levy of taxes on imports by federal authority; and it relinquished (1786) its claims to all remaining western lands, except the Western Reserve, a part of Ohio. In the constitutional convention of 1787 the present system of national representation in congress was proposed by the Connecticut delegates as a compromise between the plans presented by Virginia and those presented by New Jersey.

**The 19th Century.**—For many years following the Revolution the Federalist party (*q.v.*) controlled the affairs of the state. The opposition to the growth of American nationality which characterized the later years of that party found expression in a resolution of the general assembly that a bill for incorporating state troops in the federal army would be "utterly subversive of the rights and liberties of the people of the State, and the freedom, sovereignty and independence of the same," and in the prominent part taken by Connecticut in the Hartford convention (a secret session, 1814-15, of delegates from five New England states to consider grievances against the national government and to consider revising the federal constitution) and in the advocacy of the extensive amendments proposed by it. However, the development of manufactures, the discontent of nonconforming religious sects with the establishment, and the confusion of the executive, legislative and judicial branches of government in the constitution opened the way for a political revolution. All the discontented elements united with the Democratic party in 1817 and defeated the Federalists in the state election; in 1818 a constitution remained in effect until 1965 was adopted. From 1830 until 1855 there was close rivalry between the Democratic and Whig parties for control of the state administration.

In the Civil War Connecticut was one of the most ardent supporters of the Union cause. When Pres. Abraham Lincoln issued his first call, for 75,000 volunteers, there was not a single male in company in the state ready for service. Gov. William A. Buckingham issued a call for volunteers in April 1861; and soon 54 companies, more than five times the state's quota, were organized.

After the war the Republicans were more frequently successful at the polls than the Democrats. Representation in the lower house of the general assembly, by the constitution of 1818, was based on the townships, each township having two representatives, except townships created after 1818, which had only one each. This method constituted a serious evil when, in the transition from agriculture to manufacturing as the leading industry, the population became concentrated to a considerable degree in a few large cities and the relative importance of the various townships was greatly changed. A constitutional amendment of 1828 provided that senators should be chosen by districts, and that in the apportionment regard should be paid to population, no county or township was to be divided and no part of one county was to be joined to the whole or part of another county, and each county was to have at least two senators; but by 1900 any relation that the districts might once have had to population had disappeared. This system of representation sometimes put in power a political party representing a minority of the voters. In 1878, 1884, 1888 and 1890 the Democratic candidates for state executive office received a plurality vote; but, as a majority was not obtained, these elections were referred to the general assembly, and the Republican party, in control of the lower house, secured the election of its candidates. In 1901 constitutional amendments were adopted making a plurality vote sufficient for election, increasing the number of senatorial districts and stipulating that "in forming them regard shall be had" to population.

The growth and movement of population has greatly complicated and confused the representative system. In 1774 the apportionment was not grossly inequitable, there being only six towns

with less than 1,000 inhabitants and three with more than 6,000 population. However, in mid-20th century the 11 smallest towns with a total population of 6,105 had 15 representatives whereas the six largest towns with an aggregate population of 753,046 had 12 representatives. This condition was the single most significant feature of the government of the state because it conditioned the operation of the whole system. A constitutional amendment in 1901 provided for decennial reapportionment of the senate, if necessary, but no reapportionment was made after 1903 until 1965 (see *Government* below).

**The 20th Century.**—Between 1902 and 1960, 16 amendments to the constitution were adopted: some of the most important were granting the governor power to veto specific sections of appropriation bills in 1924; and, in 1948, increasing the term, from two years to four years, of the governor, lieutenant governor, secretary-treasurer, comptroller and also of the judges of probate beginning Jan. 1951.

World War I was a period of great industrial expansion and consequent prosperity. After the Armistice, despite a recession, the state continued prosperous until the depression of the 1930s which was especially severe in Connecticut. However, conditions were improved by federal agencies, as well as by an extensive public works program undertaken by the state. A number of towns thus acquired new schools, libraries, town halls and other public buildings at about half the cost of the work in normal times. Under the same conditions many miles of dirt roads were hard-surfaced.

With the outbreak of World War II in Europe, Connecticut firms began to receive large war contracts. Employment and production reached a new peak, with continued expansion and diversification after the war.

Many important measures of social legislation were adopted after 1930, notably: systems of unemployment compensation; old-age assistance; a fair employment practices act; an act prohibiting discrimination because of racial, religious or national origin; and a minimum-wage bill. In 1937 the state administration was extensively reorganized by a series of legislative acts which increased the powers of the governor, established a department of finance and control and put the employees of the executive department under the merit system.

An interracial commission was established in 1943 and a housing authority the same year. The Connecticut turnpike, which skirts Long Island sound from New York to Rhode Island, was opened in 1958. Two laws of major importance were passed by the general assembly in 1959. The first abolished the county governments as of Oct. 1, 1960, the necessary county functions being transferred to the state government. The second law revised the local court systems. The municipal court judges and the justices of the peace were replaced on Jan. 1, 1961, by a new circuit court system. The circuit court was composed of 44 full-time judges, one of whom would be the chief judge.

In Connecticut politics, Dwight D. Eisenhower, heading a Republican sweep in 1956, received the largest plurality of any presidential candidate in Connecticut history. In 1958, however, Democratic Gov. Abraham Ribicoff (elected U.S. Senator in 1962) was re-elected in the largest election landslide in the state's history. In addition to all of the elective state offices, the Democrats controlled the general assembly for the first time in 82 years and filled all vacancies in the U.S. congress, six representatives and a senator. In 1960 the state's electoral votes went to John F. Kennedy and in 1964 to Lyndon B. Johnson, both Democrats. (E. E. Sz.)

## GOVERNMENT

From 1662 to 1818 Connecticut lived under a charter granted by King Charles II of England. In 1818 the voters approved a new constitution which remained in effect until 1965. As a result of a Federal court order to redistrict and reapportion the two houses of the general assembly according to population, a constitutional convention convened July 1, 1965, and completed the drafting of a new constitution in October. On Dec. 14 the voters approved this document.

The new constitution required the house of representatives to

have from 125 to 225 members (actually 177 under bipartisan agreement); the senate, from 30 to 50 (actually 36). The old system had 36 senate districts very unequal in population. House members (294) represented towns with even greater inequalities. To prevent indefinite continuation of existing districts, the new constitution provided that the assembly at its first regular session after the decennial census redistrict each house as necessary to be "consistent with federal constitutional standards." In case the assembly fails to redistrict by April 1 following the census, provision was made for a bipartisan commission of eight to carry out the task. Members of both houses serve two-year terms. Since 1950 the term of governor, lieutenant governor, and four other executive officials has been four years.

The new constitution introduced several additional major changes. It strengthened the governor's powers by increasing from a simple majority to two-thirds the vote required to override a veto. The formerly mandatory use of party lever on the voting machines was made optional. A new article gave towns, cities and boroughs a guarantee of home rule. A new section in the Bill of Rights prohibited segregation or discrimination in exercise of civil or political rights because of religion, race, colour, ancestry or national origin. The amendment process was changed to permit either house to initiate action. Proposals approved by three-fourths of the members of each house go to voters at the next general election. Proposals receiving a majority but less than three-fourths must be passed by a majority of both houses at the next regular session before submission to the voters. In either case a majority of those voting at the general election is necessary for adoption. The legislature was given authority to summon a constitutional convention once every 10 years. If the legislature fails to call a convention within 20 years, the question of holding a convention must be submitted to the electorate.

The judges of the supreme court and the superior court, appointed by the general assembly on the governor's nomination, serve for eight years, and the judges of the court of common pleas, chosen likewise, serve for four years. Probate judges are elected for four-year terms.

Qualifications for the suffrage are: age of 21 years, residence in the state for one year and in a town (township) for six months, a good moral character and ability to read in English any article of the constitution or any state statute.

Connecticut local government centres around 169 townships and 23 cities. In townships executive officers usually are a first selectman and two other selectmen—all chosen biennially. Business is transacted at a town meeting in which all voters may participate. Fifteen towns have a town manager system. There are twelve boroughs which are separate districts within a town with their own separate government, but also subject to the town government. Connecticut has 23 cities of which 20 have a mayor-council system, and 3 a city manager. (A. E. V. D.)

**Finance and Taxation.**—The principal sources of state revenues are motor vehicle licences, gasoline taxes, sales and use taxes, a tax on insurance companies and an inheritance tax. There is no personal income tax. State and local governments spend about 29% of their revenues on education, nearly 33% on highways, about 5.5% on public welfare and slightly more than 7% on health and hospitals. The state's income in the second half of the 20th century was more than four times as great as it had been prior to World War II, but expenditures had increased nearly five times. Prior to 1938, Connecticut had no bonded indebtedness. Per capita income has been well above the national average for many years.

## POPULATION

The population of Connecticut in 1790, the year of the first federal census, was 237,946. Its population ranked eighth among the 18 states and territories that then composed the union and was classified as 97% rural. Between 1830 and 1840 the state grew at the slowest rate in its history. In 1840 the population was only about 4% greater than it had been in 1830. By mid-19th century the population was 370,792, which made Connecticut the 21st most populous state out of 37. It remained largely rural in

character as approximately 84% of its inhabitants were classified as nonurban. From 1850 to 1860 the population increased at the highest rate in the state's history until the 1950 to 1960 decade. The census of 1860 showed an advance of 24.1% over that of 1850. By 1900 the state had 908,420 inhabitants and was ranked 29th among the states and territories in the federal census of that year. The 50 years between 1850 and 1900 more than halved the rural population—in 1900 only 40% of the population was classified as rural, reflecting the growing industrialization of the New England area to which Connecticut belongs. The entire urban population in 1960 which included also the thickly settled suburban areas, or "urban fringe," amounted to 1,985,567 persons or 78.3% of the state total. The nine standard metropolitan statistical areas (Bridgeport, Hartford, Meriden, New Britain, New Haven, New London-Groton-Norwich, Norwalk, Stamford and Waterbury) in 1950 contained nearly three-fourths of the total population. In 1960 these metropolitan areas housed 77.6% of the total population. In 1960 Connecticut had a population of 2,535,234, an increase of 527,954, or 26.3% over 1950. The population per square mile in 1960 was 506.1, as compared with 49.7 for the U.S. as a whole.

By the second half of the 20th century, Connecticut was one of the most highly urbanized states in the U.S. None of the Connecticut cities was very large, but the size of the cities was not a true index of the degree of urbanization of the state, because the state constitution made annexation of new territory by the cities nearly impossible and most urban communities had outgrown the legal city limits. Suburban growth in the metropolitan areas was a more reliable measure of the extent of urbanization. Thus, more than 69% of the population of the Hartford metropolitan area was to be found outside the city of Hartford. One reason for the increasing urbanization is the fact that Connecticut lies in the path of the great coastal urbanized zone extending from Norfolk and Richmond, Va., to Portland, Me.

In spite of the architectural and monumental evidences of its colonial origins, Connecticut was no longer the land of the Puritan,

or even the Yankee. Nearly half of the population was foreign born or of foreign or mixed native and foreign parentage. There had been an infusion of substantial numbers of Polish, Italian, Irish, French Canadian, English, Canadian, German, Swedish and Lithuanian immigrants. In addition about 50,000 Negroes lived in the state.

The population of the state was distributed by colour and nativity in 1960 as follows: 84.9% native white; 10.7% foreign-born; and 4.2% native nonwhite. There were 96.3 males per 100 females in the white population and 95.6 in the nonwhite population; 8.3% of the population was 65 years old or over; and 42.2% of the population 14 years old and over was the labour force.

Of the total number of employed, 1.8% was engaged in agriculture, 5.6% in construction and 40.3% in manufacturing.

## EDUCATION

**Historical.**—Soon after the foundation of the colonies of Connecticut and New Haven, schools similar to the English grammar schools were established. The Connecticut code of 1650 required all parents to educate their children, and every township of 50 householders (later 30) to have a teacher supported by the men of family, while the New Haven code of 1656 also encouraged education. In 1672 the general court granted 600 ac. of land to each county for educational purposes; in 1794 the general assembly appropriated the proceeds from the sale of western lands to education, and in 1837 made a similar disposition of funds received from the federal treasury. Beginning on July 15, 1909, the organization of public education was changed from the district type to town management type. Appropriations for the support of the schools are made at a town meeting.

In 1941 regional schools were authorized. Under this law two or more towns could join in establishing a school for the participating towns. In addition to local support for schools, the state aided its schools by making various grants from time to time. In 1947 a new school grant law was passed which aimed at a minimum expenditure of \$140 per pupil. Ten years later, the state achieved an expenditure of \$341 per pupil. This was considerably higher than the national average and 11th highest in the country. In 1938, the state appropriated about 6% of its income for educational purposes, but after World War II, two and one-half times as much was being spent.

**Higher Education.**—Originally, the New England settlers had intended to establish institutions of higher learning in all of the colonies. With this objective in mind, the general court of the New Haven colony met in 1648 to choose a site for a college. Massachusetts, where Harvard university had been founded in 1636, objected to the plan for a new college on the grounds that New England could not support more than one college. Thus it was not until 1701 that the Rev. James Pierpont and ten other clergymen formed the nucleus of what was to become Yale university. The general assembly supported the Pierpont plan and a site for the school was chosen at Saybrook. However, until 1701 classes met at Killingworth (Clinton). The college was moved from Saybrook to New Haven in 1716. In 1718 the school took the name of Yale after Elihu Yale who had financially assisted the college. It was the first institution of higher learning in the United States to grant the degree of doctor of philosophy (1861) and was the first to establish a school of fine arts (1869). In 1960 the institution had an endowment of approximately \$195,000,000 and a library containing nearly 4,250,000 books.

Other private colleges in Connecticut included Albertus Magnus college, New Haven (Roman Catholic, 1925); Anshurst college, South Woodstock (Roman Catholic, 1941); University of Bridgeport, Bridgeport (nonsectarian, 1927); Fairfield university, Fairfield (Roman Catholic, 1942); Quinnipiac college, Hamden (nonsectarian, 1929); St. Joseph college, West Hartford (Roman Catholic, 1932); Trinity college, Hartford (Episcopal, 1823); and Wesleyan university, Middletown (nonsectarian, 1831). The University of Connecticut, Storrs (1881), university and land-grant college, has undergraduate branches at Hartford, Stamford, Waterbury and Torrington; schools of law and of social work and a college of insurance are at Hartford. Other state-supported colleges

‡Windsor township which includes Willimantic city.

§Windsor township which includes Winsted city.

Note: Dash indicates place did not exist during the reported census, or data not available.

are Danbury State college, Danbury (1903); Southern Connecticut State college, New Haven (1893); Central Connecticut State college, New Britain (1849); and Willimantic State college, Willimantic (1889). The federal government maintains the United States Coast Guard academy at New London (1876). In Feb. 1957 the state's general assembly chartered the University of Hartford (private, nonsectarian) to unite three separate degree-granting institutions: the Hartford Art school, Hartt College of Music and Hillyer college.

### HEALTH, WELFARE AND CORRECTIONS

The welfare activities of the state are under the direction of the commissioner of welfare. The activities are mainly in the categories of old-age assistance, aid to the blind, aid to the disabled and aid to dependent children. In addition, the state maintains the following charitable institutions: the Veterans' home and hospital at Rocky Hill; the Mystic Oral School for the Deaf at Mystic; Cedarcrest sanatorium in Wethersfield and Newington, Laurel Heights sanatorium in Shelton, the Seaside in Waterford, the Norwich State Tuberculosis sanatorium in Norwich and the Undercliff sanatorium in Meriden. The mental hospitals are the Connecticut State hospital in Middletown, the Norwich State hospital in Norwich and the Fairfield State hospital in Fairfield.

Two training schools for the mentally deficient and epileptic are provided by the Mansfield State Training school and hospital and the Southbury Training School.

In the field of corrections are the Connecticut State prison at Wethersfield and its adjunct, the Norris G. Osborn farm in Enfield; the Connecticut School for Boys in Meriden; the Long Lane school (for girls) in Middletown; the Connecticut reformatory in Cheshire; and the Connecticut State Farm for Women and State Prison for Women in Niantic. After 1960 the former county jails were administered by the state.

### THE ECONOMY

**Agriculture.**—Since about 1850 Connecticut has been an industrial state, but agriculture has remained of considerable economic and historical interest. More recently, while dairy, poultry and tobacco farming continued to be important, especially in the fertile Connecticut valley, agriculture as a whole has declined. The number of farms declined from about 21,000 in 1940 to about 8,000 in 1960. There was a corresponding, but somewhat slower, decline in the acreage under cultivation. Perhaps the principal cause of the decline of agriculture was urbanization which was increasing land values so greatly that farming was becoming unprofitable. In the early 1960s greenhouse and nursery products and tobacco were the most valuable crops. Potatoes and tomatoes were other important commodities. However, the poultry industry and dairy products provided the largest agricultural income.

**Industry.**—Manufacturing is notable for its early beginning. Iron products were manufactured throughout the 18th century, nails were made before 1716 and were exported from the colony, and it was in Connecticut that cannon were cast for the continental troops and the chains were made to block the channel of the Hudson river to British ships. As early as 1732 the London hatters complained of the competition of Connecticut hats in their trade. Tinware was manufactured in Berlin, Hartford county, as early as 1740, and tin, steel and iron goods were peddled from Connecticut through the colonies.

The Connecticut clockmaker and clock peddler was the 18th-century embodiment of Yankee ingenuity. The most famous of the clockmakers were Eli Terry (1772–1852), who made a great success of his wooden clocks; Chauncey Jerome, who first used brass wheels in 1837 and founded in 1844 the works of the New Haven Clock company; Gideon Roberts and Terry's pupil and successor, Seth Thomas (1786–1859), who built the factory at Thomaston carried on by his son Seth Thomas (1816–88).

From 1802 brassworks were in operation at Waterbury—the great brass manufacturing business there growing out of the making of metal buttons.

In 1768 paper mills were erected at Norwich, and in 1776 at East Hartford. In 1788 the first woolen mills in New England

were established at Hartford and, about 1803, 100 merino sheep were imported by David Humphreys, who in 1806 built a mill in that part of Derby which is now Seymour and which was one of the first New England factory towns.

The period of greatest development of manufacturing began after the War of 1812. During the period 1850–1900, when the population increased 145%, the average number of wage earners employed in manufacturing establishments increased 248.3%, the number so employed constituting 13.7% of the state's total population in 1850 and 19.5% of that in 1900.

Connecticut usually ranks first among the states in the production of felt hats, firearms, clocks, silverware, nonferrous metal products, office machines, tools and insulated wire and cable. Other products manufactured in large quantities include needles, pins, brass products, ball bearings, typewriters, springs, hooks and eyes and slide and snap fasteners.

The growth of industry is illustrated by the fact that about half of the 1,000,000 employed persons in the state in the 1960s were engaged in manufactures, three-fourths of the factory workers being engaged in metalworking industries.

The depression of the 1930s was felt very severely in the state. At its height in 1933 there were only 2,410 industrial establishments working in the state compared with 4,571 in 1919. By 1939, however, recovery was general and during World War II the state received government contracts in excess of \$8,000,000,000 and facility contracts in excess of \$553,000,000. After the war industry continued to grow, exceeding its pre-depression peaks in numbers both of establishments and employees.

**Transportation and Communication.**—Transportation of products is facilitated by water routes and about 800 mi. of railways. Electric railways, which developed swiftly after 1895 and reached a peak mileage of 1,618 in 1922, had almost disappeared by mid-20th century. The state highway system, one of the best in the U.S., in 1960 was composed of nearly 3,400 mi. Connecticut's share of federal aid, under the comprehensive Federal-Aid Highway act of 1956, amounted to nearly \$30,000,000 for the fiscal year 1961. The Merritt parkway and its continuation, the Wilbur Cross highway, provided quick motor travel from the New York line across the state to Massachusetts, most of it by a four-lane divided highway. A feature of this superhighway is the tunnel under West Rock ridge at New Haven. The Connecticut river is spanned by five bridges, four of modern type, allowing unimpeded transportation on the river.

About 25 daily newspapers were published, of which the *Hartford Courant*, founded in 1764, is one of the oldest in the United States. The state was also well supplied with standard and FM radio stations and television outlets.

**Minerals.**—The mineral industries of Connecticut have had a declining fortune. The early settlers soon discovered metals and began to mine them. About 1740 the production of iron became an important industry in the vicinity of Salisbury, and from that iron many of the American military supplies in the Revolutionary War were manufactured. Copper was extensively mined at Newgate. Some of the mines were worked during World Wars I and II when prices were high, but in peacetime operation became uneconomical. The quarries of granite near Long Island sound and those of sandstone at Portland and of feldspar at Branchville and South Glastonbury have furnished building materials. For many years, however, the greatest source of income from minerals has been ledges of traprock. The crushed stone obtained from them largely accounts for the state's excellent roads. Stone and crushed stone and sand and gravel for construction comprise more than 90% of the state's annual mineral production, which increased steadily from less than \$5,000,000 in 1940 to more than \$20,000,000 in the 1960s. Connecticut produces small but significant amounts of mica and calcium metal.

**Fisheries.**—The fisheries, at mid-20th century, were not so important as formerly. Stream pollution was partially responsible for this. The raising of seed oysters had become the most important activity. Flounder, scup and shad were the chief fishes still exploited commercially.

See also references under "Connecticut" in the Index.

**BIBLIOGRAPHY.**—A. Johnston's *Connecticut* (1887) contains a bibliography of Connecticut history up to 1887. Some histories are E. B. Sanford, *A History of Connecticut* (1922); C. M. Andrews, *Connecticut's Place in Colonial History* (1924); G. L. Clark, *A History of Connecticut: Its People and Institutions* (1914); N. G. Osborn (ed.), *History of Connecticut in Monographic Form* (1925). Other works of value are P. W. Bidwell, *Rural Economy in New England at the Beginning of the Nineteenth Century* (1916); R. J. Purcell, *Connecticut in Transition*, rev. ed. (1918); C. H. Douglas, *The Government of the People in the State of Connecticut*, rev. and rewritten by L. S. Mills (1926).

Works dealing with colonial and early history are B. Trumbull, *A Complete History of Connecticut from 1630 to 1764* (1804-18); E. E. Atwater, *History of the Colony of New Haven* (1881); and the monograph of C. H. Levermore, "The Republic of New Haven," and that of C. M. Andrews, "The River Towns of Connecticut," in *Johns Hopkins University Studies* (1886-89). For the sources, see *Colonial Records of Connecticut* (1850-90); *The Records of the Colony and the Plantation of New Haven* (1857-90); *The Records of the Colony and the Plantation of New Haven* (1857-58) and *Records of the State of Connecticut* (1894 et seq.). *The Collections* (1860 et seq.) of the Connecticut Historical Society contain valuable material, especially the papers of Gov. Joseph Talcott, and the *Papers of the New Haven Colony Historical Society* (1865 et seq.) are extremely valuable for local history; but a vast number of documents relating to the colonial and state periods, now in the state library at Hartford, have never been published. For law and administration, consult the work of Douglas given above; the last two chapters on "The Constitution and Laws of Connecticut" in *New England States* (1897); "Town Rule in Connecticut" in *Political Science Quarterly*; B. Steiner's *History of Education in Connecticut* (1893); and the reports of the administrative boards and officials, especially those of the bureau of labour statistics, the board of education, the board of charities and the treasurer. The physical features of the state are treated in W. M. Davis's *Physical Geography of Southern New England* (1895) and the *Bulletins* of the State Geological and Natural History Survey Commission.

The following important works on Connecticut have appeared: J. M. Morse, *A Neglected Period of Connecticut's History, 1818-1850* (1933); I. M. Calder, *The New Haven Colony* (1934); C. M. Andrews, *Colonial Period of American History*, 4 vol. (1934-38), of which the chapters relating to Connecticut are excellent for the topics covered; F. S. M. Crofut, *Guide to the History and Historic Sites of Connecticut*, 2 vol. (1937), containing accounts of all towns in the state and extensive bibliography; *Supplementary List* (1938) of more than 1,000 titles, prepared by A. C. Bates; *Connecticut: A Guide to Its Roads, Lore and People*, "American Guide Series" (1938); C. W. Burpee, *Story of Connecticut*, 4 vol. (1939); O. Shepard, *Connecticut, Past and Present* (1939); L. S. Mills, *Story of Connecticut* (5th ed., 1958); W. S. Lee, *Yankees of Connecticut* (1957); O. Zeichner, *Connecticut's Years of Controversy, 1750-1776* (1949). The Committee on Historical Publications of the State Tercentenary commission issued a series of 60 monographs of topical history (1933-36); *The Connecticut Guide* was compiled by E. L. Heermance (1935). (E. E. Sr.)

**CONNECTICUT RIVER**, the longest river in New England, has its origin in Third Connecticut lake near the New Hampshire-Canadian border. After flowing about 9 mi. through New Hampshire it becomes the border between New Hampshire and Vermont for about 238 mi. and then crosses Massachusetts and Connecticut to Long Island sound. Total length of the river is 407 mi.; basin area 11,085 sq.mi. The 23 principal tributaries that flow into it are mostly short, swift streams in narrow valleys dotted with small power dams, storage ponds and factories. The lower 60 mi. are tidal and there is a 15-ft. channel to Hartford, Conn. The total fall in the river (2,190 ft.) and in its tributaries is so fully utilized it is one of the most completely developed streams in the U.S. in terms of hydroelectric power.

The upper course of the Connecticut river flows across complex metamorphic rocks overlain by terraced lacustrine deposits dotted with dairy farms, and between the foothills and plateaus bordering the Green mountains, the White mountains and the eastern upland. In much of Massachusetts and Connecticut the river has cut a wider valley in the softer Triassic shales and sandstones where tobacco, dairy and truck farming are important.

The Connecticut valley has been traveled by Indians, colonists, soldiers, traders, educators, farmers and manufacturers for 200 years. Its significance as a manufacturing region is attested by the cities of Hartford, Conn. (aircraft, machine tools), Springfield and Windsor, Vt., and Claremont, Lebanon and Newport, N.H. (machine tools, ball bearings), the paper-producing centres of Groveton and Claremont, N.H., Ryegate, Vt., and Windsor Locks, Conn., and dozens of communities producing woollens and worsteds and products of the forests. (A. S. Cn.)

**CONNECTING ROD:** see LINKAGES; INTERNAL-COMBUSTION ENGINE.

**CONNECTIVE AND SUPPORTING TISSUES**, a group of tissues that support and bind together the organs, which in turn form the animal. All connective and supporting tissues have the same embryological origin, the mesoderm of the embryo. Though the connective tissue appears in different forms in different parts of the body, there is a fundamental similarity in the components, and any particular modification of form represents an adaptation to function.

Every organ has its capsule and stroma (a mattress) of connective tissue. The entire body is supported by the skeleton. Muscles are closely associated with tendons, connective tissues that transmit the mechanical force of muscle contraction to the bones, which are the levers. The lever function of bone is dependent on connective tissue in several ways: in the ligaments that hold together the joints; the cartilage that surfaces the joints; and the synovial membrane that lines the margins of the joint cavity and lubricates and nourishes the joint surfaces. The nourishment of tissues generally is closely associated with the connective tissue. In it are located the blood vessels. All nutrient materials and waste products exchanged between tissue cells and blood stream must traverse the intercellular spaces, and these spaces are filled with and maintained by the connective tissue.

**Components of Connective Tissue.**—Three major components are demonstrable and can be recognized in almost every one of the connective tissues thus far examined. These are: (1) the cells; (2) the extracellular fibres; and (3) the extracellular, non-fibrillar ground substance. It is the fibrillar and ground substance material, present in great abundance, that gives the connective tissues their main characteristics. The usual anatomical classification of connective tissues is based upon the appearance, situation and tactile quality of the several different types. These qualities are in turn related to the microscopic and molecular structure of the interstitial components and to the relative proportions of the several components or the particular component that predominates. Thus the hardness of bone is due to the heavy deposition of lime salts in the fibrous matrix; the toughness and flexibility of cartilage (gristle) is caused by the presence of an abundant jellylike material embedded in a tough fibrous matrix and the ropelike tensile strength of tendon is related to the dense bundles of collagen fibres of which tendon is composed.

**Cells.**—At one stage in its development the embryo of any vertebrate animal is composed of three primary germ layers, ectoderm, mesoderm and endoderm. Almost all the epithelial (that is, covering and lining) structures of the organism arise from the ectoderm and endoderm. The connective tissue of the body, with the exception of that in the central nervous system, is derived from a subdivision of the mesoderm called mesenchyme (middle infusion). Mesenchyme is a loose, soft tissue that infiltrates between the various structures in the body that are developing from the other sources. The cells of the mesenchyme have great potentiality for further differentiation. They eventually produce all the various cells of adult connective tissue. In the adult animal some fixed undifferentiated mesenchymal cells remain as a reserve source of the more highly specialized types. In form they resemble fibroblasts.

Fibroblasts are the most characteristic cells of nonrigid connective tissue. They are large cells with an elongated form having processes extending out from the cell-body. These cells probably produce the major components of the collagen fibril. The macrophage (also called histiocyte), another cell type, has the property of phagocytizing particulate and colloidal material. Some students believe that these cells are capable under conditions of stress (e.g., inflammation) of transforming into lymphoid cells or into fibroblasts. The reticular cells are a type seen mainly in tissues such as lymph nodes, spleen and bone marrow. They are associated with the reticular fibres, which form a main structural component of bone marrow, spleen and lymph nodes. These cells constitute a reserve of undifferentiated precursors for certain blood cells, and probably differentiate into the reticulo-endothelial cells. Reticulo-endothelial cells line certain blood

channels (sinusoids) in spleen, liver, lymph node and bone marrow, and have the capacities of phagocytosis and formation of reticulum fibres. Mast cells are found in connective tissues throughout the body. They secrete heparin and histamine. It is likely that they play an important role in relation to the function of the small blood vessels in vertebrates. Eosinophil cells are present and are particularly abundant in certain inflammatory conditions, mainly those presumed to be of allergic origin. The functions of the eosinophil had not been ascertained as of the early 1960s.

Plasma cells are common in the connective tissues, particularly the serous membranes and lymphatic tissue. They have been associated with the formation of antibodies.

Fat cells are a prominent component of certain connective tissues and may be the predominant cell type. They are characteristic and have a large globule of fat surrounded by a thin rim of cytoplasm (cell sap), containing the compressed elongated nucleus. Fat has several functions—as a storage depot of fatty acids and other substances for metabolic purposes; as a packing material in certain parts of the body such as the orbit of the eye, the spaces between muscles and between organs; as an insulating material against cold and physical stress beneath the skin.

Pigment cells have small dark-brown granules of melanin. These cells, called dermal chromatophores, are present in skin and probably receive their pigment from the epithelium.

Chondrocytes and osteocytes are special forms of connective tissue cells and are the main cells of cartilage and bone respectively.

**Fibrillar Substance.**—There are three main types: collagen, reticular and elastic fibres.

Collagen fibres are best seen in the tendon. They are white in the fresh state, relatively inelastic and of great tensile strength. These are the main constituents of the connective tissue layer of the skin, the dermis. Chemically treated (tanned) dermis is leather. Collagen is composed of groups of fibres varying in width from a few to several hundred microns. The individual fibres do not branch. Bundles of fibres have longitudinal striations and, after treatment with alkali, can be teased into fine fibrils. The electron microscope has shown that such a fibril is composed of even finer filaments. These filaments show a regular periodic structure with the main elements (bands) spaced  $64\text{ }\mu\text{m}$  apart. A still finer banding with a periodicity of  $21\text{ }\mu\text{m}$  has also been seen. It has been possible to dissolve the collagen of skin and tendon in weak acetic acid or in sodium citrate and by appropriate measures cause fibrils to reform. These have essentially the same periodic structure as the native collagen. Collagen dissolves in hot water and the product is gelatin. Native fibres are digested by pepsin and collagenase, a specific enzyme produced by certain bacteria. It is not digested by trypsin. The main component of collagen is a protein; it contains a large quantity of the amino acid, hydroxyproline, which makes it almost unique among proteins. The birefringence of the fibres indicates an orderly structure. It has been deduced from the chemical analysis and X-ray diffraction patterns that there is a periodic arrangement of the amino acids in a coiled chain. How the fibres are formed in life is not known. They are probably formed extracellularly from a precursor made in the fibroblast. A polysaccharide component probably forms a cement substance between the fibrils.

Reticular fibres are a fine extracellular fibrillary substance in the supporting stroma of many organs. They characteristically branch and join with one another to form a reticulum (network). They differ from collagen fibres in that they are not birefringent. Reticular fibres like collagen are dissolved by pepsin and collagenase. In the electron microscope the reticular substance is seen as a membrane composed of fine randomly oriented fibrils lying in an amorphous matrix. The fibrils show the main periodic banding of  $64\text{ }\mu\text{m}$  characteristic of collagen. The amino acid composition of the protein of reticular fibres is similar to that of collagen in having a high hydroxyproline content. Reticular substance protein is soluble in boiling water but no gel is formed on cooling concentrated solutions. Reticular fibres have a more abundant carbohydrate matrix than collagen.

Elastic fibres are characteristically yellow in adult animals.

The fibres are long, narrow, branch and frequently are arranged in plates or perforated membranes as in the walls of large arteries. There is no fibrillar pattern visible in them. They are not birefringent until stretched. They are resistant to hot water, strong alkali and trypsin digestion. They are digested by the enzyme elastase found in the pancreas. During digestion by this enzyme fine intertwined fibrils appear with a diameter of  $25\text{ }\mu\text{m}$ . These are twisted together to form the larger fibres. Elastic fibres are composed of protein differing in composition from collagen and reticular fibres and probably have a fatty component. These fibres are like rubber bands—when stretched they snap back to their original state. They impart elasticity to such structures as lung, blood vessel walls, tendons and cartilage.

**Amorphous Ground Substance.**—This is the material that lies between and around the fibres and cells. It is most clearly seen in cartilage, in the Wharton's jelly of the umbilical cord and in the vitreous humour of the eye. Large carbohydrate molecules designated acid mucopolysaccharides form an important part of ground substance. The properties of two have been well established: (1) hyaluronic acid is composed of glucuronic acid and an amino sugar related to glucose, N-acetyl glucosamine; and (2) chondroitin sulfuric acid A is composed of equimolecular portions of N-acetyl chondrosamine, glucuronic acid and sulfuric acid. Other compounds of similar structure also have been found.

Solutions of hyaluronic acid are very viscous. The viscosity is reduced when the material is exposed to an enzyme, hyaluronidase, found in many bacteria and in extracts of sperm. When preparations of this enzyme are injected into the skin of animals it enhances the spreading of viruses, bacteria and other particulate matter injected simultaneously in the same location.

Ground substance is a gel composed of these large sugars, protein and salts. All substances passing to and from cells must pass through the ground substance; therefore, variations in its state and composition must have a rather profound influence on the life of the individual cells and tissues.

**Anatomical Types of Connective Tissues.**—**Areolar Tissue.**—This is composed of cells, collagen and elastic fibres in a loose arrangement with wide spaces filled with amorphous ground substance. Loose connective tissue is widely distributed as a whitish sticky mass in spaces between organs and following blood vessels into the interior of organs.

**Adipose Tissue.**—Adipose or fat tissue is a variant of loose areolar tissue in which fat cells are the major constituent. It is concentrated in certain regions of the body as indicated above. (See ADIPOSE TISSUE.)

**Dense Fibrous Tissue.**—This is composed of closely packed bundles of collagen, some elastic tissue fibres and their associated fibroblasts. Little amorphous ground substance is present. The fibres may be arranged in parallel bundles as in the tendons or may be disposed in several planes interwoven with one another to form a dense cohesive tissue. This is the character of the deeper layer of the skin, the dermis, and is also seen in the capsules surrounding the joints. Macrophages and undifferentiated mesenchymal cells are present.

**Synovial Membranes.**—These membranes are tubelike structures surrounding joints and closely applied to margins of joint surfaces. They are composed of thin vascular connective tissue. The synovial cells secrete a viscous fluid, synovial fluid, containing hyaluronic acid, protein and salts. This serves as a nutrient and lubricant for the joint surfaces. Tendon sheaths are similar structures surrounding tendons where they pass over bony prominences. (See JOINTS AND LIGAMENTS.)

**Cartilage.**—This group of substances represents nature's solution to the problem of constructing an almost rigid material that will withstand compression. Three types of cartilage are recognized anatomically. These are hyaline, elastic and fibrocartilage.

The glassy appearance of hyaline cartilage is due to the character of the large intercellular component. The fibrillar component, collagen, is immersed in a firm amorphous gel. A large element in this gel is chondroitin sulfate. Within this matrix the cartilage cells, chondrocytes, are situated in spaces called lacunae. With the exception of the surfaces of the joints, all cartilage is

surrounded by a membrane, the perichondrium, having an outer layer of fibrous tissue and an inner layer of flattened chondroblasts (forerunners of cartilage cells). This layer merges imperceptibly with the main cartilage mass.

New cartilage is formed in one of two ways—interstitial growth, by division of cells within lacunae, and appositional growth, by proliferation of new cells from the perichondrium. In the development of the vertebrates the skeleton is first laid down as hyaline cartilage and is gradually removed and replaced by bone. In the adult, hyaline cartilage is found in the articular cartilages at the ends of the long bones, in the costal cartilages uniting sternum to ribs and forming the flexible portions of the nose, the tracheal rings and bronchi. All forms of cartilage are without an integral blood supply; all nutrients and waste material travel to and from the cells by diffusion from vessels in the perichondrium or fluid in the joint space. This places a limitation upon the size which cartilaginous structures can attain. With advancing age the cartilage matrix may become calcified. Such a deposit is a usual thing in the superficial portions of the skeleton of cartilaginous fishes. Elastic cartilage contains, in addition to collagen, elastic fibres. This type is present in the external ear and the epiglottis, parts which are subjected to frequent bending as well as compressive stress.

Fibrocartilage is like hyaline cartilage except for a larger component of collagen fibres. These fibres are usually oriented in a plane parallel to the pull made on the structure, and the chondrocytes are disposed in rows between the fibre bundles. This cartilage has greater tensile strength than the other types. It is found in the intervertebral discs, at the edge of joint surfaces and at tendinous insertions to bone. (See also CARTILAGE.)

**Bone.**—The structure of bone is an elegant adaptation of components of simpler forms of connective tissues in the development of large supporting members for vertebrate animals. There are bones strong enough to support the weight of an elephant and others light yet rigid enough to give form and adequate leverage for wings of large birds.

Two formations are found in bone. The cortex (periphery) of bone is commonly compact osseous tissue, while cancellous or spongy bone is found in the medulla (marrow). Spongy bone consists of tubes, plates and bars forming a network. This network conforms accurately to the directions and lines of maximum pressures and tensions. The tubes, plates and bars, called trabeculae, are made up of a varying number of closely adjoining bone plates or lamellae. Within the interstitial substance are small spaces, lacunae, within which lie the osteocytes (mature bone cells). Lacunae intercommunicate with each other through a network of canaliculi (fine channels). The canaliculi of marginal lacunae extend to the surface of a trabecula. Small trabeculae have no blood vessels in them. They are bathed in the tissue fluid of the surrounding marrow, and from this through the canaliculi comes the nourishment to the osteocytes in the lacunae. The canalicular system can carry fluid at an adequate rate over only a relatively short distance. Hence the thickness that nonvascular trabeculae attain is limited. Trabeculae thicker than 0.2 mm. have blood vessels in special canals and the lacunar canaliculi communicate with vascular spaces.

Compact bone has a rich vascular network that is disposed in the framework of the bone in a system of tubes, Haversian systems, having laminated walls. The walls of the canals have a composition and structure identical to that of the trabeculae.

The intercellular substance of bone is collagen imbedded in a cement substance impregnated with calcium salts. The main component is calcium phosphate in the form of hydroxyapatite crystals. Carbonates and magnesium salts lie in the cement substance associated with these crystals. Osteoblasts form the fibres, the cement substance and phosphatase, an enzyme liberating inorganic phosphate from compounds (esters) of phosphate. Calcium in tissue fluid unites with free phosphate liberated locally in high concentration to form insoluble calcium phosphate crystals. In this way osteoblasts form about themselves their bony encasement, leaving projections in canaliculi. As mature osteocytes, they maintain the bone structure.

Bone is constantly being resorbed. How resorption occurs is not clear. The process is continuous in the absence of osteoblasts and osteocytes. Osteoclasts, once thought to be responsible for bone resorption, are believed to be degenerating osteoblasts which fuse to form these multinucleated giant cells.

Two types of bone formation, intramembranous and endochondral, are recognized. The fundamental process is similar in both. Intramembranous formation is observed in the bones of the skull, which are formed in a connective tissue membrane whence osteoblasts arise and produce bone. Endochondral formation is seen in the major part of the skeleton, which is formed first in a cartilage model. Vascular connective tissue from the perichondrium invades the cartilage model, which undergoes a series of transformations including preliminary calcification and dissolution of cartilage matrix and lacunae. On the residual spicules of calcified cartilage new bone is formed.

This type of formation is seen in the diaphysis (shaft) of a long bone and continues in the epiphyseal plate at the end of the long bones until growth of the bones is complete (28th year in man). Epiphyseal growth is by formation of new cartilage at the outer ends of the plate and ossification on the inner. Circumferential growth of bone is of intramembranous type from the periosteum. Bone is a living object. It is maintained and remodeled under continuous stress via the processes outlined.

All bones have cortex (an outer rind) and more or less medulla (spongy central cavity). In the medulla is the bone marrow. Yellow (fatty) marrow is present in the shaft of long bones. Red marrow is the site of formation of the red and white cells of the blood; mixed with a variable quantity of fat, it is present in the ends of long bones, vertebral bodies, ribs and sternum.

See BONE; BONE MARROW; SKELETON; VERTEBRATE; see also references under "Connective and Supporting Tissues" in the Index volume.

See A. W. Ham and T. S. Leeson, *Histology*, 4th ed. (1961); A. A. Maximow and W. Bloom, *Textbook of Histology*, 7th ed. (1957). (E. P. Br.)

**CONNECTIVE TISSUE, DISEASES OF** (COLLAGEN DISEASES) are those maladies in which the connective tissue is involved diffusely. The connective tissue (its nature and functions are discussed in the article CONNECTIVE AND SUPPORTING TISSUES), because of its uniform morphologic composition and functional activity, can be regarded as a biologic system of the body or even as an organ, although it is dimly dispersed throughout the living organism. It can be affected locally by inflammation, or its cells, stimulated to excessive growth, may form local benign or malignant neoplasms. Because of their localized character such morbid processes are not included in the concept of connective tissue or collagen diseases, the term being restricted to diseases in which the tissue is implicated diffusely.

The morphological criteria upon which the term collagen disease is based are alterations of the intercellular substances of the connective tissue, the collagenous extracellular fibres and, above all, the homogenous ground substance. The hallmark of the structural changes is a characteristic microscopic appearance, commonly referred to as fibrinoid connective tissue damage, caused by the deposition within the homogenous ground substance of a substance microscopically similar to but not identical with fibrin. The small blood vessels in various parts of the body are frequently and conspicuously affected by the deposition of this abnormal material. It is undoubtedly of glycoprotein nature, but the proteins concerned have not been adequately identified.

According to the definition of connective tissue diseases given above, the following maladies may be included: rheumatic fever, rheumatoid arthritis, generalized necrotizing arteritis (periarteritis nodosa), diffuse scleroderma, systemic lupus erythematosus and possibly dermatomyositis. These clinically and pathologically well-defined diseases are similar in that they all show systemic alterations of the intercellular connective tissue components and that their etiology is largely unknown. These similarities, however, do not justify the assumption that the fundamental nature of the diseases is identical. In the past they were often regarded as being engendered by hypersensitivity. The

hypothesis was proposed because fibrinoid connective tissue damage has been provoked in animals made hypersensitive to foreign proteins. But later experiments demonstrated that similar lesions, particularly fibrinoid vascular lesions, can be elicited by other, different mechanisms, such as constant or transient vascular hypertension. Furthermore, histopathologic investigations of these diseases indicate that the fibrinoid substances in the individual maladies are not identical in their chemical constitution.

The apparent similarity therefore does not justify the assumption that there is a common factor which unites these diseases etiologically. A disease is diagnostically well defined only if its basic cause and the mechanism by which it provokes the clinical symptoms and the characteristic structural alterations are known. The term connective tissue diseases has often been misconstrued. It has no diagnostic validity and reflects only the heuristic concept that systemic alterations of the connective tissue are meaningful for the comprehension of the aforementioned maladies, and that further investigations should aim at the disclosure of all the factors responsible for these tissue changes. (P. Kr.)

**CONNELLY, CORNELIA** (1809-1879), U.S. religious, founder of the Society of the Holy Child Jesus and centre of an acrimonious ecclesiastical controversy in the mid-19th century, was born Cornelia Peacock in Philadelphia, Pa., Jan. 15, 1809. She was brought up as an Episcopalian and married at the age of 22 an Episcopalian clergyman, Pierce Connelly. While serving as rector of Trinity church, Natchez, Miss., Connelly became interested in the Roman Catholic Church, study of which led to the conversion of both him and his wife by 1836. In 1840 Connelly became convinced that he had vocation to the priesthood, and his wife was encouraged to separate from him and become a nun. This mother of four children signed the deed of separation in 1844 and took up residence in the Sacred Heart convent of Trinità dei Monti in Rome. Connelly was ordained in 1845.

In 1846 Bishop Nicholas Wiseman asked Mrs. Connelly to come to England and found an order for teaching English girls. The first house was opened, and in 1847 she took religious vows and was installed as first superior of the Society of the Holy Child Jesus. When she refused to allow her husband any participation in the new congregation he filed suit in the English courts for restitution of conjugal rights. Failing to win his case, he left the Catholic Church and began a campaign of vilification that lasted until his death. Cornelia Connelly bore it all with great equanimity and equal determination. She died in England on April 18, 1879. Renewed interest in her work and virtues in the 20th century broke what was almost a conspiracy of silence following the publicity of the controversy.

See *The Life of Cornelia Connelly* (1922) by a member of the Society; Juliana Wadham, *The Case of Cornelia Connelly* (1956).

(E. R. V.)

**CONNEMARA**, an area in County Galway, Republic of Ireland, lies west of Galway city and Loughs Corrib and Mask; area 302.6 sq.mi. It is a country of ancient rocks which has been scoured of its earth by ice sheets, strewn with large stones and blocks of rock left by the ice, and mainly covered with peat bog. From the coastal lowland, running west for over 20 mi. from Galway, the land rises gradually to over 1,100 ft.; this area is traditionally called Iar Connacht and extends to Berraghboy bay which has numerous islands. The largest of these islands, Lettermore, Gorumna and Lettermullan, are linked with the mainland by road. West of the bay the true Connemara begins, with a fine varied coast, scores of islands, vast peat bogs, hundreds of lakes and, to the north of the Clifden-Galway road, the sharp jagged-peaked quartzite ranges of the Twelve Bens and the Maamturks with numerous summits over 2,000 ft. high. The population lives mainly in a belt a mile or so wide from the shore, where the land was laboriously made from sand, seaweed and other manures, with small fields protected by high walls. Connemara ponies are numerous in the coastal area. The only town is Clifden (pop. [1956] 986), at the end of the 50-mi.-long road from Galway. This remote market town was the terminus of a light railway from 1895 to 1935 and once a small port. Roundstone is a small village and seaside resort. The government has introduced some light indus-

tries and a peat-fired power station at Screeb, on Berraghboy bay. Under a tomato-growing plan, greenhouses have been built on many of the farms.

(T. W. Fr.)

**CONNOLLY, JAMES** (1870-1916), Irish socialist who played a decisive part in launching the Easter rising of 1916, was born in County Monaghan on June 5, 1870. He was the first dynamic advocate of socialism in Ireland and became an ardent apostle of class warfare among the miserably underpaid women workers in Belfast and the dock labourers in Dublin and other ports. He was James Larkin's chief assistant in organizing the Irish National Transport Workers union, which aimed at enrolling all Irish workers in support of every labour dispute. After experiencing many such "sympathetic strikes," the Dublin employers determined to break Larkin's union by a ruthless lockout (1913). Connolly, with his formidable energy and intellectual gifts as a journalist and editor, gave powerful support to Larkin's campaign for help from the British trade unions. Labour demonstrations were brutally dispersed, and Connolly organized a citizen army at Liberty hall. On the outbreak of World War I in 1914 Larkin was in the United States and Connolly assumed charge. He soon committed the Irish labour movement to opposing the Allied war effort, claiming that peace could come only through the overthrow of all capitalist states. His reckless impatience to start an armed rising in Dublin caused much anxiety to the Irish Republican brotherhood, which was secretly planning the insurrection for Easter 1916. The plans miscarried at the last minute, but Connolly insisted that some attempt must be made, however hopeless. P. H. Pearse and other leaders set out with him from Liberty hall to capture the general post office, where the Irish republic was first proclaimed. The rising was put down with much bloodshed and Connolly was executed at Kilmainham jail on May 12, 1916.

(D. G.)

**CONNOR, RALPH** (pen name of CHARLES WILLIAM GORDON) (1860-1937), Canadian clergyman and writer of popular fiction. The son of a Highland Scottish Presbyterian minister, he was born at Indian Lands in Glengarry county, Ont., on Sept. 13, 1860. After graduating from the University of Toronto in 1883, he studied divinity at Knox college (Presbyterian), Toronto, and the University of Edinburgh. Ordained in 1890, he became a missionary in mining and lumbering camps of the Canadian Rockies. This experience and memories of his Glengarry childhood provided the major background for his fiction. He was minister of St. Stephen's church in Winnipeg, Man., from 1894 to 1936. During World War I he became a senior chaplain in Flanders. He was one of those instrumental in the formation of the United Church of Canada in 1925.

Skill in compounding a religious message with wholesome sentiment and adventure made his first book *Black Rock* (1898) a best seller. Also popular were *The Sky Pilot* (1899); *The Man From Glengarry* (1901); *Glengarry School Days* (1902); *Corporal Cameron of the North West Mounted Police* (1912); *The Sky Pilot in No Man's Land* (1919); and *The Girl From Glengarry* (1933). He died in Winnipeg on Oct. 31, 1937. His autobiography *Postscript to Adventure* appeared in 1938. (G. H. Ro.)

**CONNOTATION.** That the meaning of a name may not be identified with its *denotation* (see NAME [IN LOGIC]) is readily made clear by means of examples. Thus "the Morning Star" and "the Evening Star" are two names of the same planet. It would be possible, however, to know the meaning of both names and even to have seen and identified the Evening Star on one occasion and the Morning Star on another, without knowing that they are the same. For it is not apparent from casual examination of the heavens that the Morning Star and the Evening Star are the same, but this was rather an early astronomical discovery established by a series of careful observations. Once this discovery is made, it is natural to introduce a third name, "Venus," to mean *the heavenly body which is the Morning Star and is the Evening Star*. But this same planet has also other names, for example, "the second planet from the sun." And to see that this name and the name "Venus" have different meanings, it suffices to remark that if an intra-Mercurial planet were discovered, we would not then say either that Venus does not exist or that Venus is the planet which was

previously called Mercury, but only that we were mistaken in supposing Venus to be the second planet from the sun. But if it should be found that, by some unimaginable error, the Morning Star and the Evening Star are after all not the same, we would then indeed be obliged to say, Venus does not exist.

In the light of this, the names "the Morning Star," "the Evening Star," "Venus," "the second planet from the sun" are said to have each a different *connotation* (or *sense*). But if accepted astronomical facts are correct, the four names have the same denotation.

The distinction of connotation and denotation was introduced by J. S. Mill in 1843. And a similar distinction of sense (German *Sinn*) and denotation (German *Bedeutung*) was introduced by Gottlob Frege in 1892, without reference to Mill.

Mill has the credit of having discovered this important distinction of two kinds of meaning. But Mill's treatment is in several respects less satisfactory than Frege's. In particular, Mill applies the distinction primarily to common names and (unlike Frege) denies connotation altogether to a large class of singular names, including all simple abstract singular names such as "courage," "whiteness." And it was Frege who first pointed out the equivocal usage of natural language by which a name, besides its ordinary use, may have in some contexts an *oblique* use, denoting the same which in its ordinary use it connotes.

See further MEANING, and SEMANTICS IN LOGIC. (Ao. C.)

**CONOID**, in geometry, any surface traced by a conic section (*q.v.*) rotating around either of its axes. Hence there are more varieties of conoids than of conics. These include: (1) The ellipsoid, which may be (*a*) a prolate spheroid, shaped like a lemon, formed when an ellipse rotates around its major axis, or (*b*) an oblate spheroid, shaped like the earth, formed when the rotation is around the minor axis; a special limiting case is (*c*) the sphere, formed when the ellipse becomes a circle, all diameters then being equal. Archimedes (*c.* 287–212 B.C.) preferred the term spheroid to ellipsoid. (2) The paraboloid, generated by a parabola rotating about its axis. All rays emerging from the focus would be parallel to the axis and would be reflected from the paraboloid, considered as a mirror, as one immense beam—whence the construction of paraboloidal reflecting surfaces in automobile headlights and reflecting telescopes. (3) The hyperboloid, either of one sheet (*nappe*), formed by rotation around the conjugate axis; or of two symmetric congruent sheets, formed when rotation is around the transverse axis. See ANALYTIC GEOMETRY; ELLIPSOID; PARABOLOID; HYPERBOLOID; SURFACES.

The equations of the conoids are:  $x^2 + y^2 + z^2 = a^2$ , for the sphere;  $x^2/a^2 + (y^2 + z^2)/b^2 = 1$ , for the prolate spheroid;  $(x^2 + z^2)/a^2 + y^2/b^2 = 1$ , oblate spheroid;  $y^2 + z^2 = 4px$ , for the paraboloid;  $(x^2 + z^2)/a^2 - y^2/b^2 = 1$ , for the hyperboloid of one sheet;  $x^2/a^2 - (y^2 + z^2)/b^2 = 1$ , for the hyperboloid of two sheets.

**CONON** (d. 687), pope from 686 to 687, was probably the son of a Thracian soldier. Brought up in Sicily and ordained in Rome, he was elected in his old age to succeed John V. Consecrated on Oct. 21, 686, he died Sept. 21, 687.

**CONON** (d. *c.* 390 B.C.), son of Timotheus, Athenian general. After having held several commands during the Peloponnesian War, he superseded Alcibiades as admiral in 406 B.C. He was defeated by the Spartan fleet and blockaded in Mytilene. The Athenian victory at Arginusae rescued him (406), and as he had not been present at the battle, he was not tried with the other generals. In 405 when the Athenian fleet was defeated at Aegospotami, Conon escaped to Cyprus. On the outbreak of the war between Sparta and the Persians (400) he obtained from Artaxerxes II (*q.v.*) joint command with Pharnabazus of a Persian fleet. In 394 he defeated the Spartans near Cnidus, and thus deprived them of supremacy at sea. He restored the long walls and the fortifications of the Piraeus. Imprisoned by Tiribazus when on an embassy from Athens to the Persian court to counteract the intrigues of Sparta, Conon probably died in Cyprus about 390.

**CONON** (fl. at Rome, second half of 1st century B.C.), grammarian and mythographer, was the author of a collection of Greek myths and legends, a number of which referred to the foundation of colonies. The work, dedicated to Archelaus Philopator, king

of Cappadocia, contained 50 *Narratives*; an epitome, with brief criticisms, has been preserved in the works of the Byzantine scholar Photius. Nicolaus of Damascus is said to have made considerable use of the *Narratives*.

See U. Hofer (ed.), *Konon* (1890).

**CONON OF SAMOS**, Greek astronomer and geometer (3rd century B.C.), made astronomical observations in Italy and Sicily, but settled in Alexandria. He was the friend of Archimedes, who survived him.

Conon is best known in connection with the Constellation Coma Berenices (Hair of Berenice). Berenice, the wife of Ptolemy Euergetes had in accordance with a vow dedicated her hair in the temple of Arsinoë of Zephyrium as an offering on the safe return of her husband from his Syrian expedition. It disappeared from the temple, and was declared by Conon to have been placed among the stars. Callimachus wrote a poem on the subject, of which only a few lines are preserved, but the imitation of it by Catullus is extant.

Conon wrote on astronomy in seven books, and made a list of the observations of solar eclipses recorded in Egypt. He also investigated the question of the maximum number of points of intersection of two conics, and of a conic and a circle.

**CONQUEST**, in traditional international law, refers generally to the acquisition of territory by the victorious state in a war at the expense of the defeated state. Some authorities identify conquest with the provisional occupation of territory resulting from successful military operations, and describe the legal process of transferring title as "subjugation," if the defeated state is totally annexed by the conqueror, or as "cession," if the defeated state retains its identity and agrees by treaty to the alteration of the territorial status quo in favour of the victor. According to another view, the term conquest is dissociated from the physical appropriation of territory during hostilities and used as a synonym for subjugation as described above.

In either case, conquest is associated with the principle of traditional international law that sovereign states may resort to war at their discretion and, by military victory, achieve territorial and other gains that will be recognized as having legal validity. The state acquiring territory by conquest is regarded as the successor, with certain qualifications, to the rights and duties previously appertaining to the territory. Private rights, interests and property in the territory are not affected by the change of sovereignty, and legal rules applicable to such matters remain in effect until altered by the legislative authority of the new sovereign.

The international legal significance of the doctrine of conquest and its derivative rules has been challenged in the 20th century by the development of the principle that aggressive war is contrary to international law. This change may be traced through the covenant of the League of Nations, the Kellogg-Briand pact of 1928, the charters and judgments of the International Military tribunals created at the end of World War II to try war criminals of the Axis powers, and numerous other multipartite treaties, declarations and resolutions. The logical corollary to the outlawry of aggressive war is the denial of legal recognition to the fruits of such war; this implication was officially drawn by the United States government in the Stimson doctrine, enunciated by Secretary of State Henry L. Stimson on Jan. 7, 1932. It was subsequently affirmed by the assembly of the League of Nations and on several occasions by conferences of the American republics. The draft declaration on rights and duties of states, formulated in 1949 by the International Law commission of the United Nations, contained in article 11 the rule that states are obligated not to recognize territorial acquisitions achieved by aggressive war.

Nevertheless, it would be premature to assert that the traditional provisions of international law regarding the rights derived from conquest have been abandoned. Wars, legal or illegal, and the changes in the actual possession and control of territory, and the modifications of legal principle effected since World War I have not diverted states, in practice, from the tendency to give legal acknowledgment to actual alterations of territorial boundaries even those achieved by allegedly illegal warfare.

See also AGGRESSION; ANNEXATION.

(I. L. C.)

**CONRAD**, the name of four German kings, one of whom was also western emperor.

**CONRAD I** (d. 918) belonged to the powerful Franconian dynasty known as the Conradines, who had annihilated their local rivals, the Babenbergs. On Nov. 10, 911, he was elected German king at Forchheim after the death of Louis the Child, the last of the East Frankish Carolingians. It is not clear whether Conrad was supported by all the German nobles east of the Rhine or only by the Franks and Saxons. The Lotharingian nobles, however, turned to the West Frankish Carolingian, Charles III. In 913 Conrad married Kunigunde, a member of the Alaholfing family of Swabia. His reign was a bitter and bloody struggle to uphold the traditions of Carolingian kingship against the growing power of the Saxon, Bavarian and Swabian stem leaders. His attempt to mobilize the episcopate in this cause at the synod of Hohenaltheim (916) could not compensate for the adverse balance of his campaigns. Conrad was in fact unable to establish his family as the new royal house in the East Frankish kingdom, and shortly before his death (Dec. 23, 918) he is reported to have proposed his opponent, the Liudolfing Henry of Saxony, as his successor.

**CONRAD II** (c. 990–1039), German king and western emperor, the first king of the Salian dynasty, was the great-grandson of the emperor Otto I's daughter Liudgard and Conrad the Red. After the early death of his father, Count Henry of Speyer (d. c. 1000), Conrad received little of the family's fiefs and allods in Rhenish Franconia; and the emperor Henry II for a time saw in him an enemy. His election to the throne in 1024 by an assembly which recognized his exalted lineage was opposed by a group of Lotharingian princes and prelates, who proposed a younger cousin and namesake of Conrad's as king. He was, however, able to disarm their opposition as well as Saxon recalcitrances, and in 1026 he went to Italy, being crowned emperor in Rome on March 26, 1027. Back in Germany, he broke the rising of his stepson, Duke Ernest of Swabia, by drawing the loyalties of his vassals to himself. Perhaps the future of the kingdom of Burgundy was at stake in this conflict, as the empress Gisela, who descended from the Welf kings of Burgundy, was Conrad's wife and Ernest's mother. When King Rudolf III, the last of the Welfs, died in 1032, Conrad succeeded to Burgundy and thus secured control over the western Alpine passes. On the eastern frontiers of the *Reich* the emperor's campaigns and negotiations more or less restored German ascendancy over Poles, Bohemians and the heathen Slav tribe of the Liutizi. A second expedition to Italy (1036–38) failed to subdue a Milanese rising in support of Archbishop Aribert, whom Conrad had had deposed. The German army was greatly weakened by disease, and Conrad himself died at Utrecht on June 4, 1039.

The characteristic features of Conrad's reign were a tight-fisted acquisitiveness which rebuilt and enlarged the royal demesne and the advancement of a class of unfree royal servants known as *ministeriales*. Their functions in the king's household and their military services became increasingly important at this time. Lastly, though Conrad had risen from the middling lay aristocracy and was new to the theocratic ideas and practices of Ottonian kingship, the crown's reliance on the church did not grow any less. The contradictions between his role as "king and priest" and his lay warrior habits did not pass unnoticed among contemporaries, and he was the first emperor whose rough ways of using the personnel and wealth of the church were attacked on principle by reformers. Yet Conrad was the most successful king of his dynasty. He brought back to the throne something of the down-to-earth temperament of the early Saxon rulers before their new, cosmopolitan connections and the predominance of their learned clerical advisers had alienated them culturally from their feud-hungry nobles.

(K. J. L.)

**CONRAD III** (1093–1152), German king, second son of Frederick I, duke of Swabia, and Agnes, daughter of the emperor Henry IV, was the first king of the Hohenstaufen family. In 1105 his father died and in 1106 his mother married Leopold III, margrave of Austria. In 1115 his uncle the emperor Henry V appointed him duke of Franconia. In 1116, together with his elder brother Frederick II, duke of Swabia, he was left by Henry as regent of

Germany, and when the emperor died in 1125 Conrad doubtless expected his brother to succeed to the throne. But the 40 electors, rejecting the hereditary principle, chose Lothair, duke of Saxony, an enemy of the Salian dynasty. By the end of the year Frederick and Conrad were in revolt, and on Dec. 18, 1127, Conrad was elected antiking at Nürnberg. Hastening across the Alps, he was crowned king of Italy at Monza in June 1128, and in spite of the papal ban was generally acknowledged in northern Italy. The rival popes Innocent II and Anacletus II both declared against him; the Romans repudiated him; and after failing to seize the extensive possessions left by Matilda of Tuscany he returned to Germany in 1132. He continued the struggle against Lothair till 1135, when he submitted, was pardoned and recovered his estates. In 1136 he accompanied the imperial forces to Italy as standard-bearer, and sought to win the favour of Pope Innocent II.

In Dec. 1137 Lothair died. A number of the electors meeting at Coblenz chose Conrad as his successor on March 7, 1138, in the presence of the papal legate. Crowned at Aix-la-Chapelle six days later, he was acknowledged at Bamberg by several of the South German princes; but Henry the Proud, duke of Bavaria and Saxony, the son-in-law and heir of Lothair, refused his allegiance. Conrad, for his part, refused to recognize Henry's claim to Saxony on the ground that no one should hold two duchies at once. Attempts at a peaceful settlement of this rivalry failed. Henry was placed under the ban of the empire and deprived of both his duchies in July 1138. War broke out in Bavaria and Saxony and Conrad was unable to make much headway, in spite of Henry's death (Oct. 1139). The king's half-brother Leopold IV (d. 1141), margrave of Austria, to whom Bavaria had been entrusted, was defeated by Henry the Proud's brother Welf, later duke of Spoleto and margrave of Tuscany. Conrad, however, defeated Welf at Weinsberg in Dec. 1140, and peace with the Welf family followed at Frankfurt in May 1142: Henry the Lion, son of Henry the Proud, was confirmed in the duchy of Saxony, while Bavaria was given to Conrad's half-brother Henry Jasomirgott, margrave of Austria, who married Gertrude, widow of Henry the Proud. In spite of this peace the rivalry of the Welfs and the Hohenstaufen dominated German history for the rest of the century.

The solitary success amid the general disorder in the empire was Conrad's expedition into Bohemia in 1142, where he restored his brother-in-law Vladislav II as prince. An attempt to perform the same service for another brother-in-law, the Polish prince Wladyslaw (son of Boleslaw III), ended in failure. There was great disorder in Saxony, Bavaria and Burgundy; and in 1146 war broke out between the Bavarians and the Hungarians.

Bernard of Clairvaux's preaching, however, sent many turbulent nobles on the second crusade, thus providing some respite. In Italy Roger II, king of Sicily, had won considerable authority on the mainland and refused to recognize the German king, while Pope Lucius II implored Conrad's help against the rebellious Romans. Conrad allied himself with the Byzantine emperor Manuel Comnenus, who in 1146 married his sister-in-law; but Conrad's departure on the second crusade prevented the contemplated campaign against Roger. In Dec. 1146 Conrad took the cross, secured the election and coronation of his young son Henry as his successor, appointed Henry I, archbishop of Mainz, as his son's guardian and, in the autumn of 1147, set out for Palestine. Marching with a large and splendid army through Hungary, he reached Asia Minor, where his forces were decimated by disease and defeat. Stricken by illness, Conrad returned to Constantinople at Christmas 1147, but set out to rejoin his troops in March 1148. Having shared in the fruitless attack on Damascus, he left Palestine in Sept. 1148 and passed the winter at Constantinople, where he consolidated his alliance with the Byzantine emperor for an attack on Roger of Sicily. He reached Italy by sea; but the news that Roger had allied himself with Louis VII of France and with Welf of Bavaria forced Conrad to hurry back to Germany. He was detained there and could not visit Rome, in spite of invitations from the Romans; thus he never received the imperial crown.

Conrad died on Feb. 15, 1152, at Bamberg, where he was buried. By his wife, Gertrude, daughter of Berengar, count of Sulzbach,

he had two sons, the elder of whom, Henry, died in 1150. Passing over his younger son Frederick on account of his youth, he designated as his successor his nephew Frederick III, duke of Swabia, afterward the emperor Frederick I Barbarossa.

(X.; R. H. C. D.)

**CONRAD IV** (1228–1254), German king from 1237 and king of Sicily from 1251, was born at Andria in Apulia on April 26, 1228, the son of the emperor Frederick II and his second wife, Isabella (Yolande) de Brienne. Heir to the kingdom of Jerusalem through his mother, he was also invested by his father as duke of Swabia in 1235. At Vienna in Feb. 1237 he was elected king of the Romans in place of his half-brother Henry VII, who had rebelled against the emperor in 1235. After Pope Gregory IX had excommunicated Frederick II in 1239, Conrad was opposed by a growing papal party in Germany, led by the archbishops Siegfried of Mainz and Conrad of Cologne. In 1245 Pope Innocent IV declared both Conrad and his father deposed and proclaimed a crusade against them. On Aug. 5, 1246, Conrad was defeated near Frankfurt by the antiking Henry Raspe. He continued to be supported, however, by the towns and by Otto II of Bavaria, whose daughter Isabella he married on Sept. 1, 1246. On Dec. 13, 1250, Frederick II died. Troubles in Sicily and the rising strength of the papal party in Germany under Henry Raspe's successor, William of Holland, forced Conrad to abandon Germany for Sicily late in 1251, when he took the title of king of Sicily. Conrad's position in Sicily was secured by his capture of Naples in Oct. 1253, but his efforts to reach an understanding with the papacy failed. Preparing to march to Germany through central Italy he died at Lavello on May 21, 1254.

**CONRAD THE RED** (d. 955), duke of Lotharinga and ancestor of the Salian dynasty of German kings, belonged to a family of Franconian counts with a rich patrimony in the country round Speyer and Worms. In the aftermath of the first great rising (937–939) against King Otto I he supported Otto and became one of his closest followers. Otto gave him the duchy of Lotharinga (see LORRAINE) in 944 and his daughter Liudgard in marriage three years later. From Lotharinga, Conrad assisted the Carolingian ruler of France, Louis IV, against Hugh the Great and others. He accompanied Otto on his first expedition to Italy in 951 and was left in charge there. When the king refused to back his policy of reconciliation with the defeated but not powerless Italian ruler Berengar II, Conrad joined his already disaffected brother-in-law, Liudolf of Swabia, and with a host of other malcontents they rose in rebellion (953–954). The rebels were at first successful, but a Hungarian invasion which they were accused of having instigated turned the scales against them. Conrad had to submit and lost his duchy but not his lands in Franconia nor his vassals. He fell at the battle of the Lechfeld on Aug. 10, 955, when the largest Hungarian army to enter Germany was de-

stroyed; it seems that his services were decisive in giving Otto his great victory.

(K. J. L.)

**CONRAD, JOSEPH** (JÓZEF TEODOR KONRAD NALECZ KORZENTOWSKI) (1857–1924). Polish-born writer who became one of the greatest novelists in the English language, was born at Berdichev in the Polish Ukraine, then under Russian rule, on Dec. 3, 1857. His father, a landowner of literary tastes, was exiled to northern Russia for participation in the movement for Polish independence; both Conrad's parents died before he was ten, leaving him in Cracow in the care of his uncle, Tadeusz Bobrowski.

Conrad first had the idea of going to sea in 1872, a strange decision for one whose family had no nautical tradition and whose country had no seacoast. At 17, he went to Marseilles, from where he twice sailed in French ships to South America. On his return he became involved in gunrunning for the forces of Don Carlos, pretender to the Spanish throne, and in a passionate love affair, both of which episodes he treated in *The Arrow of God* (1919), a novel which found favour with few critics. An unsuccessful attempt at suicide brought this period of his life to an end. After his recovery he shipped in an English vessel and landed at Lowestoft, Suffolk, in 1878, speaking only a few words of the language of which he was to become a recognized master.

He rose in the merchant service and in 1886 received his master mariner's ticket and his certificate of naturalization, shortly afterward obtaining his first command. During this period and for some years thereafter he served mostly in those eastern waters which were to form the background of his early works, though he also made one voyage up the Congo. He was at the time writing his first novel, *Almayer's Folly* (1895), and the experiences of the journey, which later took shape in his conte, *Heart of Darkness* (1902), were of immense significance to him. "Before the Congo" he once wrote in a letter, "I was just a mere animal." *The Mirror of the Sea* (1906), one of his two volumes of reminiscence, bears witness to the importance for him of his life as a sailor, and of the satisfactions of the stern duties which it laid upon him.

*Almayer's Folly* was followed in 1896 by *An Outcast of the Islands*, which repeats many of its themes. These two novels provoked a misunderstanding of his talents and purpose which dogged him the rest of his life. Set in the Malayan archipelago, they caused him to be labeled a writer of exotic tales, a reputation which a series of novels and short stories about the sea—*The Nigger of the "Narcissus"* (1897), *Lord Jim* (1900), *Youth* (1902), *Typhoon* (1903) and others—seemed only to confirm. But words of his own about the *Nigger* give the real reason for his choice of settings: "the problem . . . is not a problem of the sea, it is merely a problem that has risen on board a ship where the conditions of complete isolation from all land entanglements make it stand out with a particular force and colouring." This is equally true of his other works; the latter part of *Lord Jim* passes in a jungle village not because the emotional and moral problems which interest Conrad are those peculiar to jungle villages, but because there Jim's feelings of guilt, responsibility and insecurity—feelings common to mankind—work themselves out with a logic and inevitability which are enforced by his isolation. It is this purpose, rather than a taste for the outlandish, which distinguishes Conrad's work from that of many novelists of the 19th and early 20th centuries. They, for the most part, are concerned to widen the scope of the novel, to act, in Balzac's phrase, as the natural historians of society; Conrad aims at the isolation and concentration of tragedy.

It must be remembered also that he was a writer who drew extensively on his own experience, and that when he began writing he was more familiar with ships and tropical harbours than with London streets. He settled on shore in 1893, never making a specific decision to give up the sea, but finding that writing demanded his whole attention.

In 1896 he married Jessie George, by whom he had two sons. He was granted a small Civil List pension, but gave it up when the sales of his books assured his livelihood. Nevertheless he did not achieve popular success until the publication of *Chance* in

1913. His health was uncertain—he suffered from rheumatic gout which resulted from his voyage up the Congo—and his letters show the financial anxieties which beset him. Nor did writing come easily. He produced 13 novels, 2 volumes of memoirs and 28 short stories, many of considerable length, before his death at Bishopsbourne, Kent, on Aug. 3, 1924, and hardly one was written without agonizing struggles. He said when he completed the book which critics consider his masterpiece, "*Nostromo* is finished; a fact upon which my friends may congratulate me as upon a recovery from a dangerous illness."

Such a choice for his masterpiece would hardly have been made in his lifetime. In his own day he was praised for his power to depict life at sea and in the tropics and for qualities of "romance"—a word seeming generally to mean his power of using an elaborate prose style to cast a film of illusory splendour over somewhat sordid events. His reputation diminished after his death and revival of interest in his work directed attention to different qualities and, inevitably, to different books.

An account of the themes of some of these books should indicate where modern critics lay emphasis. *Nostromo* (1904), a story of revolution, politics and financial manipulation in a South American republic, centres, for all its close-packed incidents, upon one idea—the corruption of the characters by the ambitions which they set before themselves, ambitions concerned with the silver which forms the republic's wealth and which is the central symbol around which the novel is organized. The ambitions range from simple greed to idealistic desires for reform and justice. All lead to moral disaster, and the nobler the ambition the greater its possessor's self-disgust as he realizes his plight.

*Heart of Darkness*, which follows closely the actual events of Conrad's Congo journey, tells of the narrator's fascination by a mysterious personage who, by his eloquence and hypnotic personality, dominates the primitive savages. Full of contempt for the greedy traders who exploit the natives, he cannot deny the power of this figure of evil who calls forth from him something approaching reluctant loyalty. *The Secret Agent* (1907), a sustained essay in the ironic, deals with the equivocal world of anarchists, police, politicians and *agents provocateurs* in London. One of its chief characters, Mrs. Verloc—probably Conrad's most successful study of a woman, free from his usual sentimentally chivalrous adoration of his heroines—has a philosophy which underlies all these books; she believes that "things don't bear looking into very much."

Conrad's view of life is indeed deeply pessimistic. In every idealism are the seeds of corruption and the most honourable men find their unquestioned standards totally inadequate to defend them against the assaults of evil. It is significant that he repeats again and again situations in which such men are obliged to admit emotional kinship with those whom they have expected only to despise. This well-nigh despairing vision is embodied in the themes, the characters, the style and the symbolism of the works. It gains much of its force from the feeling that Conrad accepted it reluctantly; not with morbid enjoyment. "Believe me," Conrad wrote in a letter, "no man paid more for his lines than I have."

It was perhaps inevitable that such a vision was so desolating for him that he wished to deny it and, in such later works as *Chance*, *Victory* (1915) and *The Rover* (1923) this complex presentation of the good man haunted by an evil shadow is usually replaced by conflict between unbelievably good and unbelievably wicked men, expressed in lush rhetoric—always a temptation to Conrad—in an attempt to make it more convincing. But in four or five novels and rather more short stories Conrad presents an intense if, some would say, a one-sided vision of the world which places him among the greatest of English writers, and it is on these earlier works that his reputation is likely to rest.

Jean-Aubry, *Life and Letters of Joseph Conrad* (1927), the standard work, has errors of fact and emphasis which are corrected by later works; Jocelyn Baines, *Joseph Conrad, a Critical Biography* (1958); M. C. Bradbrook, *Joseph Conrad* (1941); A. J. Guerard, *Joseph Conrad* (1959); F. R. Leavis, in *The Great Tradition* (1948), M. D. Zabel, in *Craft and Character* (1957); D. Hewitt, *Conrad—a Reassessment* (1952).

**CONRADIN (CONRAD THE YOUNGER)** (1252–1268), duke of

Swabia, son of Conrad IV, king of the Romans, and grandson of the emperor Frederick II, was born at Wolfstein in Bavaria on March 25, 1252. After his father's death in 1254, he inherited a claim to the kingdom of Naples, but Frederick II's natural son Manfred, who had asserted his power in the kingdom already before Conrad's death, was crowned king in 1258, a rumour having spread that Conradin was dead. In 1262 Conradin took possession of the duchy of Swabia. After Charles of Anjou (see CHARLES I of Naples), whom Pope Clement IV had invested with Sicily, had at Benevento defeated Manfred, who perished in the battle (Feb. 1266), the Italian Ghibellines appealed to Conradin to come and conquer the kingdom from Charles, and Conradin entered Italy in Sept. 1267. Meanwhile, a revolt in his favour had broken out in Sicily; and in Rome the new senator, the infante Henry of Castile, declared himself openly for him. The Ghibelline cities of Verona (where he stayed nearly three months), Pavia, Pisa and Siena welcomed Conradin, and on July 24, 1268, he made a triumphal entry into Rome. He left Rome on Aug. 14 for the kingdom; on Aug. 23, he was defeated by Charles near Tagliacozzo, after victory had been all but assured to him. He fled to Rome, but there the Guelphs were gaining the upper hand; while attempting to escape by sea, perhaps to Genoa, he was arrested at Astura and handed over to Charles. Condemned to death for treason, he was executed on the Campo Moricino in Naples, together with his faithful companion Prince Frederick of Baden, on Oct. 29, 1268. With Conradin's death, the Hohenstaufen dynasty became extinct.

**CONRAD VON HÖTZENDORF, FRANZ, GRAF** (1852–1925), the outstanding military figure and one of the most influential conservative political figures of Austria-Hungary, was born at Penzing, near Vienna, on Nov. 11, 1852. As a brigadier in Trieste in 1899 his observation of Italian Irredentist propaganda inspired him with a lasting mistrust of Italy's reliability in the triple alliance. In Trieste he also made the acquaintance of the archduke Francis Ferdinand (*q.v.*), whose ideas coincided with his own in many respects and through whose influence he was appointed chief of staff in 1906. Every spring he presented the emperor Francis Joseph with a plan for war.

Finding that the army was technically out-of-date, Conrad set himself to reorganize it, especially the artillery. His activities earned him the hatred not only of the German liberals but also of the Slavs and the Magyars, all of whom, though for different reasons, were opposed to an aggressive policy. Conrad's most serious conflict, however, was with the emperor and the minister of foreign affairs, Graf Aehrenthal. Conrad was convinced that Austria-Hungary could not avoid a conflict with Serbia and, further, that Italy must be considered as an enemy. Both before and after the annexation of Bosnia-Herzegovina he urged that the only solution of the southern Slav question would be the "preventive" annexation of Serbia. When Italy became involved in war with Turkey in 1911, he advocated a "preventive" war against his country's ally. This suggestion led to such a conflict of views with Aehrenthal that Conrad was forced to resign and was appointed inspector of the army. He was reinstated a few months later, in 1912, when events in the Balkans again grew critical.

Conrad's strategy in World War I, developed in the offensives against the Russians, is generally recognized as sound, though it was not successful. When the new emperor, Charles, took over command of the army from the archduke Frederick, he resented Conrad's assured manner and dismissed him. Conrad commanded an army group on the Italian front from March 1917 until July 1918.

Conrad's political views likewise aroused much controversy. He believed in the maintenance at all costs of the dynastic power of the Habsburgs and disregarded the probable repercussions of any military initiative on the structure of alliances. As a strategist he was bold and skilful but unlucky; his chief failing was an often faulty judgment of human character. He withdrew into pri-

vate life after 1818 and devoted himself to the composition of his memoirs: *Mein Anfang, 1878-82* (1925) and *Aus meiner Dienstzeit, 1908-18*, 5 vol. (1921-25). His military works include *Zum Studium der Taktik*, 2 vol. (1891); enlarged ed., 2 vol. (1894). He died at Mergentheim on Aug. 25, 1925.

**CONRART, VALENTIN** (1603-1675), French man of letters, first secretary of the Académie Française, was born at Valenciennes in 1603. In 1627 he became councilor secretary to the king, and about the same time he began to invite writers to his house. From this circle the Académie Française came into being. Conrart played an influential part, entertaining numerous writers, lending them money and patching up their quarrels. He died in Paris, Sept. 23, 1675.

Conrart has no claim to be considered an original writer, and published only three prefaces. He did, however, write his own memoirs (published in 1825) and some notes on grammar. Yet his influence was great. He corrected books by Antoine Godeau, Vaugelas and Perrot d'Ablancourt line by line; and these corrections, prompted by his regard for clarity, economy and purity of style, provided the model on which French classical prose was based.

See A. Bourgoïn, *V. Conrart et son temps* (1883); A. Adam, *Histoire de la littérature française au XVII<sup>e</sup> siècle*, I, pp. 239-241; II, pp. 156-157 (1948-56). (AE. A.)

**CONS, EMMA** (1838-1912), English philanthropist best known for the work she did to provide good amusement at a cheap rate at the Royal Victoria hall, later popularly known as the "Old Vic." With assistance from Samuel Morley she rescued this theatre, which had a poor reputation, from melodrama and instituted programs of music, drama and lectures.

Emma Cons was born in London on March 4, 1838. Through an acquaintance with Octavia Hill she became interested in a number of housing schemes in London and was the first lady alderman to be elected to the London county council (1888). Her legal right to stand was, however, questioned and together with the two women councilors elected in 1889 she resigned in 1890.

She died at Hever, Kent, on July 24, 1912. Her house and 26 ac. of ground were given to the National Trust. (J. Mv.)

**CONSALVI, ERCOLE** (1757-1824), Italian cardinal who as secretary of state under Pope Pius VII played a considerable role in diplomacy during the Napoleonic period and was remarkable for the liberalism of his policy under the Restoration, was born at Rome on June 8, 1757, the eldest son of a noble family. During his early years, he enjoyed the protection and patronage of the cardinal duke of York (Henry Stuart), whose diocesan seminary at Frascati he attended. Entering the papal service as a privy chamberlain in 1783, he was made a domestic prelate in 1784 and appointed to the Congregazione di Buon Governo in 1786. After judicial experience as a member of the Signatura he reached the coveted post of auditor of the Rota in 1792. This office gave him the opportunity for other administrative work and he even undertook the reorganization of the papal military forces in 1797. However, the French occupation of Rome in 1798 interrupted his career: he was at first imprisoned by the French and then went into exile.

In Nov. 1799 the conclave which was to elect a new pope met in Venice under Austrian protection. With the co-operation of the French cardinal Jean Siffrin Maury, Consalvi, who was secretary to the conclave, succeeded in avoiding the election of the Austrian candidate and procured instead that of Pius VII (March 1800). In gratitude and friendship the new pope created Consalvi a cardinal-deacon and appointed him secretary of state (a position equivalent to that of prime minister). Consalvi now carried out two important tasks, the reform of administration and the negotiation of the concordat with France (July 15, 1801). The second was the more impressive and more exacting, and Consalvi's success in obtaining concessions from Napoleon Bonaparte is perhaps best shown by the issue of the "organic articles," the device by

which Napoleon sought to interpret the concordat in a decidedly Gallican sense. The administrative reforms inside the papal states were less lasting in their effect and encountered much opposition, but Consalvi succeeded both in introducing more laymen into the administration and in making some economic and fiscal improvements.

Although Consalvi had encouraged Pius VII to take part in Napoleon's coronation as emperor, Napoleon came to consider Consalvi as his enemy in Rome and forced his resignation from the secretaryship of state (June 17, 1806). In 1809, when Napoleon abolished the temporal power of the pope, Consalvi was compelled to go to Paris. There he showed great firmness in resisting the inducements by which Napoleon's ministers sought to persuade him to give some explicit or implicit recognition to the legality and justice of the emperor's treatment of the Holy See. His resistance was carried to the point of refusing, with 12 other cardinals, to attend Napoleon's marriage to Marie Louise, since he was unwilling to anticipate any judgment that the pope might make about the validity of Napoleon's first marriage. For this he was exiled to Reims, where he remained until Pius VII came to terms with Napoleon at Fontainebleau (Jan. 25, 1813).

In 1814 Consalvi was sent as papal plenipotentiary to the congress of Vienna. He was successful in obtaining the restitution of most of the papal territories (but not Avignon or the Comtat-Venaissin) and subsequently returned to Rome to take up again the office of secretary of state. Besides presiding over the negotiation of a number of important concordats, during 1817-23, he also strove to restrain the reactionary *zelanti* among the restored hierarchy and to minimize the interference of Austria with the Holy See and its possessions. A *motu proprio* of July 6, 1816, indicated clearly his liberal intentions, and tolerance was shown to those who had served Napoleon and Joachim Murat. Unfortunately, the subversive activity of secret societies made it impossible for Consalvi to counteract the influence of the reactionary party or to press on with practical reforms such as the colonization of the Campagna. He did much, however, to embellish Rome itself.

Pope Leo XII, who succeeded Pius VII in 1823, was violently opposed to Consalvi's moderate measures and removed him from the position of secretary of state. He was appointed prefect of the Propaganda but his period of effective office was at an end. He died at Anzio on Jan. 24, 1824. There are editions of Consalvi's memoirs by J. Crétineau-Joly, 2 vol. (1864); and of his correspondence with Metternich, from 1815, by C. van Duern (1904) and with Cardinal Pacca, in 1814-15, by I. Rinieri (1903).

See E. L. Fischer, *Cardinal Consalvi* (1899); M. Petrocchi, *La Restaurazione: il cardinale Consalvi e la riforma del 1816* (1943) and *La Restaurazione romana (1815-1823)* (1943). (J. M. R.)

**CONSANGUINITY**, in law, the connection or relation of persons descended from the same stock or common ancestor, distinguished from affinity, which is the connection by reason of marriage between each of the spouses and the relations of one to the other. Consanguinity is either lineal or collateral. Lineal consanguinity exists between persons who are descended in a direct line, one from the other, such as father-son-grandson, while collateral relations, such as uncle-nephew, descend from a common ancestor but not in direct line. In the law of inheritance the degree of consanguinity is especially significant in determining the distribution of the property of a person who has died without leaving a will (see **INHERITANCE**). Consanguinity is also important in marriage law, where two persons may be so closely related that marriage between them is prohibited (see **MARRIAGE**, **LAW OF**). Similarly, sexual intercourse between persons within certain degrees of consanguinity may constitute the crime of incest (see **INCEST**). See also **INTESTATE SUCCESSION**; **KINSHIP**.

**CONSCIENCE, HENDRIK** (1812-1883), Flemish romantic novelist, who dominated the birth and development of the Flemish novel, was born at Antwerp, Dec. 3, 1812, the son of a French father and a Flemish mother. During his delicate childhood his imagination was roused by the stories told by his mother, the books he found in the attic and with which he learned to play the slapstick plays he saw at the Punch and Judy show and

reading of cheap popular literature about medieval life. After his mother's death (1820), when he and his father went to live outside the town walls, the boy discovered nature, which was to remain a constant solace and which inspired him to write the remarkable *Enige bladzijden uit het boek der natuur* ("A Few Pages From the Book of Nature"; 1846).

After several years as an assistant teacher, he enlisted in the army in 1831. He soon fell under the spell of the Campine, a quiet region of pinewoods and heather. About this time he was introduced to French romanticism and began to write French verse. Demobilized in 1836, he entered the enthusiastic literary and artistic life of Antwerp, then strongly influenced by national romanticism: he was fascinated by his country's past and wrote (1837) *In't wonderjaar* ("In the Year of Miracles") a series of 16th-century historical scenes. With *De Leeuw van Vlaanderen* ("The Lion of Flanders"; 1838)—the epic story of the revolt of the Flemish municipalities against France, and their victory at the battle of the Golden Spurs (1302)—he became not only the creator of the Flemish novel but the author of one of the outstanding novels of European romanticism.

To earn a living, Conscience then worked successively as a clerk of the provincial administration, a gardener's helper and a clerk-recorder at the Academy of Fine Arts. From 1841 to 1857 he also took an active part in local politics. After 1840 he turned more and more to an idyllic realism and wrote novels and tales about urban and rural life, often trying to point a moral—*Wat een moeder lijden kan* ("What a Mother Can Suffer"; 1844); *Siska van Roosemael* (1844); *Baas Gansendonck* (1850); *Houten Clara* ("Wooden Clara"; 1850); *De arme edelman* ("The Poor Gentleman"; 1851); as well as incomparable village idylls—*Blinde Rosa* (1850); *De Loteling* ("The Conscript"; 1850); *Rikke-tikketaik* (first published serially, 1845; as a book, 1851). At the same time his historical novels (e.g., *Jacob van Artevelde*; 1849) took a more definite shape. He was now at the height of his genius, and his works became widely known through translations. In 1856 he became district commissioner for Courtrai and in 1868, curator of the Wiertz museum in Brussels. But, although his circumstances were improved, his spendthrift manner of life and the burdens of an expensive household caused him to write more, sometimes to the detriment of his style. Some of the many books of this last period are of interest, among them *Het Goudland* ("The Land of Gold"; 1862), the first Flemish adventure-novel, and *De Kerels van Vlaanderen* (1871), a historical novel. The publication of his 100th book in 1881 led to unprecedented demonstrations, and in 1883 a statue was set up in his honour in Antwerp. He died in Brussels, Sept. 10, 1883.

Conscience's influence on his compatriots could be overestimated. He was the most important and popular author of both the literary and the national Flemish renaissance in the 19th century. His narrative art, his inexhaustible imagination, his lifelike portrayal of people and events, and, above all, his rich sensibility, go far to compensate for the impurities of his language and his restricted means of expression. His historical novels will stand comparison with those of Sir Walter Scott, the elder Dumas, and Victor Hugo and Manzoni. In his rural tales he deliberately simplifies and purifies life; what Frank Harris calls his "sweet healthfulness" is a conscious expression of his idealistic philosophy. His village idylls of the Campine—real pastorals in prose—evoked a small world full of kindness and humanity, which never fails to charm the reader, who enters it as he would an unspoiled part of nature.

**BIBLIOGRAPHY.**—There are numerous translations of the individual novels into English, French and German. Collected translations include *Two Tales*, 13 vol. (1856-75) and *Tales*, 10 vol. (1888-75). Two series of letters, *Briefwisseling van, met en over Hendrik Conscience*, 1851, were ed. by A. Jacob (1913-14). See also G. Eekhoud, *Hendrik Conscience* (1881); R. Zellweger, *Les débuts du roman rustique*, 1880 (1941); E. de Bock, *Hendrik Conscience en de opkomst van de Vlaamse romantiek*, 2nd ed. (1943); F. Smits, *Henri Conscience et le romantisme flamand* (1943); G. Degroote and Jan de Schutter, *Hendrik Conscience en zijn uitgevers* (1953); G. Degroote, *Wat een schrijver lijden kan* (1957).

**CONSCIENCE**, a philosophical term used both popularly and technically in many different senses for that mental faculty which

decides between right and wrong. In popular usage "conscience" is generally understood to give intuitively authoritative decisions as regards the moral quality of single actions; this usage implicitly assumes that every action has an objective or intrinsic goodness or badness, which conscience may be said to discern much in the same way as the eye sees or the ear hears. Moralists generally, however, are agreed that in all moral judgments of this character there is an implied reference to moral laws, the validity of which is in some ethical systems the true subject matter of conscience. The part played by conscience in relation to general moral laws and particular cases will vary according to the view taken of the character of the general laws. If, on what is called the "jural" theory, these laws are regarded as deriving their authority from an external source, the operation of conscience is so far limited. It may be held to recognize the validity of divine laws, for example; or it may be confined to the deductive process of applying those laws to particular cases, known as "cases of conscience" (see CASUISTRY). If, on the other hand, the general laws are regarded as intuitive, then the discernment of them may be taken as the true function of conscience. In either theory, conscience may be understood as the active principle in the soul which, in face of two alternatives, tells a man that he ought to select the one which is in conformity with the moral law. Apart from the two functions of discerning between right and wrong, and actively predisposing the agent to moral action, conscience has further a retrospective action whereby remorse falls upon the man who recognizes that he has broken a moral law. (See CHARACTER; ETHICS.)

There are certain special uses of the word conscience. A conscience clause is the term given to a special provision often inserted in an English act of parliament to enable persons having religious scruples to absent themselves from certain services or to abstain from certain duties, such as war service as a combatant, otherwise prescribed by the act. Conscience money is the name given to a payment voluntarily made by a person who has evaded his obligations, especially in respect of taxes and the like. This usage derives from the last function of conscience mentioned above. Conscience courts were local courts, established by acts of parliament in London and various provincial towns, for the recovery of small debts, usually sums under £5. They were superseded by county courts (q.v.).

See also references under "Conscience" in the Index volume.

**CONSCIENTIOUS OBJECTOR**, one who is opposed to bearing arms or who objects to any type of military training and service. In some cases, conscientious objectors refuse to submit to any of the procedures of compulsory conscription. Although all objectors take their position on the basis of conscience, they have varying religious, philosophical or political reasons for their beliefs. Legal provision for conscientious objection is made in most of the English-speaking and Scandinavian countries, but in only a few other nations which employ compulsory conscription.

Religious objections to military service developed as a major emphasis of the Mennonites (q.v.) in various parts of Europe in the 16th century, the Society of Friends in England in the 17th century (see FRIENDS, SOCIETY OF), and in the 18th century the Church of the Brethren (q.v.) in Germany and the Dukhobors (q.v.) in Russia. These groups were persecuted at times for refusal to bear arms.

**United States.**—During the American Revolution and the American Civil War conscientious objectors were required to provide a substitute for military service or pay a commutation fee. In World War I conscientious objectors were exempted by law from combatant service. When several thousand refused to perform any type of military service they were detained in army camps and many were court-martialed. During the last five months of the war about 1,300 were assigned to agricultural or relief work.

The Selective Training and Service act of 1940 granted exemption from combatant training and service or from all military service to persons who were opposed to participation in war "by reason of religious training and belief." During World War II religious beliefs were construed by the courts to include humanitarian beliefs of atheists. A presidential report estimated that

25,000 conscientious objectors served in noncombatant duty, chiefly in the army medical corps. There were 12,000 assigned to civilian public service, where they worked in land reclamation and farm work, public sanitation, forest fire fighting, state and veterans' mental hospitals; a few served as test subjects in medical experiments. They received no pay or accident compensation. Their food and maintenance were paid by themselves or by the churches, with the exception of a few conscientious objectors who preferred to work in three government-operated camps. All religious groups were represented, but the largest numbers during World War II were the Mennonites, Seventh-day Adventists, Jehovah's Witnesses, Church of the Brethren and Society of Friends. Of the 5,800 imprisoned for violation of the Selective Service act, 4,300 were Jehovah's Witnesses. Although the provisions were broadened greatly compared to World War I, the government's policies resulted in a larger number of convictions.

The Universal Military Training and Service act of 1948 added a definition of religious training and belief as an "individual's belief in a relation to a Supreme Being involving duties superior to those arising from any human relation, but does not include essentially political, sociological or philosophical views or a merely personal moral code." Under this act recognized objectors worked for government or nonprofit agencies on approved projects contributing to the national health, safety or welfare.

By the Immigration and Nationality act of 1952 alien applicants for citizenship who declared themselves conscientious objectors to all forms of military service were permitted to become naturalized citizens of the United States. (E. J. M.)

**Great Britain.**—In World War I, when compulsory military service was brought into operation in Great Britain, any man could apply to a specially established local tribunal for exemption on the grounds that he had conscientious objection to undertaking combatant service. There was an appeal to an appeal court. Exemption might be absolute, or conditional on the applicant's engaging in some work which in the opinion of the tribunal was of national importance.

A noncombatant corps was established but many conscientious objectors refused to belong to it and it was alleged by religious bodies that during 1916–19 out of 16,000 known conscientious objectors at least 5,793 were court-martialed, and that 1,500 conscientious objectors refused to accept conditional exemption and elected to stay in prison rather than be released for alternative service. The Society of Friends established the Friends Ambulance unit which many conscientious objectors were allowed to join.

More satisfactory arrangements were made in World War II. Local tribunals were established under the National Service act of 1939, each with a judge as chairman. Three types of exemption could be granted: (1) unconditional; (2) conditional on the undertaking of civil work specified by the tribunal; (3) exemption only from combatant duties. Under the National Service act of 1941 conditionally registered conscientious objectors became liable for civil defense. Conscientious objectors registered during the war years represented 0.77% of the total number of men registered. When national service was extended to women in 1941 the provisions as to conscientious objection were applied to them. The proportion of women who so registered varied from 0.16% to 0.45% in each year.

The tribunals considered approximately 60,000 cases. They were given no guidance by statute or regulation on which to reach decisions, and each case was in their discretion subject to appeal to an appellate tribunal. About 80% of the claims for exemption were allowed. Decisions adverse to objectors resulted in about 5,700 civil prosecutions and more than 1,500 courts-martial. Under the National Service act of 1948 provision was made for placing persons subject to registration on a list of conscientious objectors. A person so registered is not liable to be called up for service. (Jn. M.)

**Other Countries.**—Legal provision for conscientious objectors is made in all countries of the Commonwealth of Nations that have conscription, and in the colonial territories. Usually, objectors may be called upon for noncombatant service and are liable to

punishment, ranging from a heavy fine to a period of imprisonment, for failure to register. In some cases they are also called upon for civil defense duties, to which no conscientious objections are allowed.

In the countries of continental Europe, practices varied widely in the early 1960s. Belgium, France, Greece, Italy, Luxembourg, Poland, Portugal, Spain, Switzerland, the U.S.S.R. and Yugoslavia had no legal provisions for conscientious objectors, and in some countries, notably France, Greece (where objectors had been shot) and Yugoslavia (where the penalty was 12 years in the mines) penalties for objectors were severe. In the U.S.S.R., although there was no legal provision, some types of objection were recognized administratively.

In the German Federal Republic, provision for conscientious objectors was made for the first time when the 1957 conscription law was passed. There was no conscription in the German Democratic Republic. All the Scandinavian countries recognized objectors, although Sweden enforced civil defense duties and allowed no appeal against them.

The only Latin-American country to recognize conscientious objectors was Paraguay, which had special regulations for Mennonites. Another interesting case was that of Israel, where women were subject to conscription unless they objected to military service on religious and moral grounds. (X.)

Field, *Pacifism and Conscientious Objection* (1945); E. L. Allen et al., *The Case for Pacifism and Conscientious Objection* (1946); F. M. Stratman, *War and Christianity Today* (1956).

**CONSCIOUSNESS.** The word "conscious" has been used in many different senses. By origin it is a Latin compound, meaning "knowing things together," either because several people are privy to the knowledge or (in later usage) because several things are known simultaneously. By a natural idiom it was often applied, even in Latin, to knowledge a man shares, as it were, with himself; i.e., self-conscious or attentive knowledge. The first to adopt the word in English was Francis Bacon (1601), who speaks of Augustus Caesar as "conscious to himself of having played his part well." John Locke employs it in a philosophical argument in much the same sense: "a man, they say, is always conscious to himself of thinking." And he is the first to use the abstract noun. "Consciousness," he explains, "is the perception of what passes in a man's own mind" (1690).

**As a Substance.**—In the early 19th century, psychology, which then began to emerge as a separate branch of natural science with a name of its own, was frequently defined as the "science of consciousness"; and the noun thus came into regular use as a convenient generic label to cover (according to William James who borrows this definition of psychology) "sensations, mental images, thoughts, desires, emotions, volitions, and the like"—in a word, all the miscellaneous elements of experience of which we are aware at any one time. The older empiricists called them "ideas" (using this term in a rather wide sense), and described them as "in the mind" or as the "basic units of the mind." And consciousness was thus treated as itself a sort of "mental stuff," a peculiar sort of substance, quite different from the material substance of which physical objects are composed.

**As an Attribute.**—Later writers used the word in a looser and more general sense. A simplified version of the old scholastic notion of a "scale of nature" led to the doctrine, most clearly formulated by Carolus Linnaeus, of three natural "kingdoms"—mineral, vegetable and animal. This recognized three progressive types of being: first, the merely material (stars, planets, the earth and its various inorganic contents), lifeless and mindless; second, material bodies characterized by life but not by sensation or voluntary movement (i.e., the plants); and finally those characterized by sensation and voluntary movement as well as life (i.e., animals and human beings). And the adjective "conscious" was adopted as the most appropriate term to designate this last group of properties. A little later it was used to characterize the difference between animals or men in their normal waking state

as contrasted with their condition when asleep, or in a coma, or under the influence of an anesthetic drug; the latter condition was then described as a state of "unconsciousness." This usage treats consciousness not as a concrete substance but as an abstract attribute, a property of the brain, according to the materialists, or of the mind, according to the Cartesian school.

However, when consciousness is regarded as either a substance or an attribute, several almost insuperable difficulties arise, partly philosophical, partly psychological. From the philosophical standpoint it would seem that, if consciousness is a self-contained entity or the attribute of such an entity, then it is difficult to understand how we can ever get outside it so as to discover the existence of physical objects; as the idealist school contended, we can know only our own "ideas." (See also IDEALISM.) From the psychological standpoint there is the further problem of determining what can possibly be the connection between mind or consciousness and the body or brain.

**As a Relation.**—These difficulties were to some extent met by an alternative analysis of consciousness, proposed by Franz Brentano (1874) and based on the old scholastic doctrine of *intentio* (ways of "intending" or referring to an object). The first British psychologists to adopt it were James Ward, in his article PSYCHOLOGY in the 9th edition of *Encyclopædia Britannica* (1886), and his pupil G. F. Stout. They and their followers emphasized that such semiabstract terms as "consciousness," "sensation" and "perception" tended to confuse two things, first the act or relation of sensing, and second the content or object sensed—i.e., the "sensum."

A similar view was elaborated by William James in *The Principles of Psychology* (1890). In opposition to the idealists, James began by arguing that relations are not "abstract constructions of the mind neither experienced nor felt" but (at least in many cases) a matter of direct experience. "So surely as relations between objects exist in nature, so surely do feelings exist to which these relations are known." When I see that the red spot A is to the right of the blue spot B, I directly perceive a space relation between the two. James then went on to point out that one such group of relations are those that are called consciousness; for example, "the relation of knowing—the most mysterious thing in the world." It is unique; and, like space relations, it can be directly apprehended. Closer introspection reveals that there are different species of cognitive relation; and James distinguishes two main modes—"direct acquaintance" (as when I am aware of the colours red and blue or of relations of space and time) and indirect cognition ("knowledge about"). Remembering, imagining, thinking and believing seem to imply the existence of other modes of cognition. Moreover, in addition to the various cognitive types, most English psychologists commonly recognize two other forms of conscious relation—the affective (e.g., being pleased or displeased with the object) and the conative (e.g., wanting the object).

As G. E. Moore, one of the first of the new realists, attempted to show in his *The Refutation of Idealism* (1903), this relational view of consciousness overcomes many of the chief philosophical difficulties inherent in the older doctrines, for it makes possible the ready acceptance of the notion that an object may continue to exist even when no longer perceived, just as a woman may continue to exist after she has been divorced from her husband. Moreover, this newer interpretation is in keeping with the general trend of modern science and modern logic. The earlier views tacitly assumed that all phenomena may be described in terms of the traditional logic of subject and predicate; i.e., substances and attributes. Modern logic, however, insists on the supreme importance of a third category over and above those of subject and predicate, namely, the category of relation; and modern science is built up by arguments that consist chiefly of relational propositions rather than of predicative propositions.

**Sense Data.**—Brentano described the objects of the cognitive relations—the things that we sense—as parts of the *physical* world. Similarly, most of the new realists held that the colour that I see when I look at my table, and the smoothness that I feel when I touch it, are parts of the surface of a real material

table. However, it is difficult to take the same view of the sounds we hear, or the pains we feel, or the illusory images seen in a mirror or in double vision. Later writers therefore, among them Stout, C. D. Broad and H. H. Price, distinguish between sensory contents that are directly apprehended and the physical objects that older writers held were in some way indirectly inferred and that most modern writers would prefer to say are "perceived" rather than "sensed." And the majority of psychologists who adopt this distinction (though not all philosophers) hold that sense data are essentially *mental*, like the "ideas" of the older empiricists. They form the contents of conscious experience, a continuous field or flowing stream, and thus constitute an important and legitimate subject for psychological study by introspection and experiment.

In his textbook James frankly recognized that the doctrine of consciousness as a unique relation or set of relations seemed to entail an irreducible duality between mind and matter, and pointed out that the excessive preoccupation of earlier psychologists with the introspective study of consciousness had often led to a misinterpretation of both human and animal behaviour. Eventually in 1904, in a famous essay headed "Does Consciousness Exist?" he completely abandoned the position he had previously held, and put forward a hypothesis of neutral monism. "The word consciousness," he maintained, "is just a loose way of indicating that certain sensory occurrences form part of my life-history." Bertrand Russell in his *The Analysis of Matter* (1927) adopted a similar view. He finds no evidence either for the subject of the cognitive relation (the mind or self) or for the cognitive relation itself. There are simply a number of self-existent events (the so-called sense data). When arranged in a causal order in space, they are described as material things; when arranged as life histories, they are called mental. Even so, Russell seems forced to admit a dualism of relations, since one type of arrangement is based on causal relations and the other on some kind of noncausal relation, never precisely specified.

Therefore, however we try to overcome or evade it, the undeniable facts of conscious awareness and its utter incongruity with the common conception of matter seem inevitably to confront us with an irreducible dualism, either of substances, attributes or relations (see BODY AND MIND). Russell himself puts the argument most clearly when he points out that while a blind man can know the whole of physical science (i.e., the science that deals with what is material) a man with normal vision is aware of many things that the blind can neither perceive nor conceive. It may be added that the increased interest in unconscious mental processes and in the study of drugs that will produce a local or general unconsciousness has in its turn led to a marked renewal of interest in the peculiar nature and conditions of conscious processes in and for themselves. (CY. B.)

**The Behaviourist View.**—In behaviourist psychology, consciousness is a concept referring in a general way to the behaviour of organisms characterized by alert awareness and responsiveness as contrasted with the lack of awareness and relative unresponsiveness of deep sleep or anesthetic coma. Between these extremes are varying degrees or levels of consciousness. A person is more conscious when he is dozing than he is in deep sleep but less conscious than he is when wide-awake solving a mathematical problem. Thus consciousness describes a state of an organism in terms of the readiness and facility of discriminative behaviour.

Consciousness defined in terms of behaviour originated in the psychology of J. B. Watson and was subsequently developed as operational or methodological behaviourism (*q.v.*). The more traditional view, still significantly embodied in everyday thinking, defines consciousness as the direct awareness or immediate experience of the contents and processes of mind. The method of observing consciousness, so defined, is introspection (*q.v.*), and introspectionist psychologists considered the chief business of a scientific study of mind to be the rigorous description of consciousness. The introspectionists' formulation by definition, however, makes consciousness a private event; no two observers can describe the same consciousness. Public confirmation of observational facts is impossible. Introspectionism accepted the fact that

children, mentally deranged persons or even the ordinary man on the street could not be depended upon to give reliable descriptions of consciousness, but the limitations of introspectionistic psychology became strikingly apparent when it was found that trained observers in the laboratory could not agree on fundamental observations. Such was the case in a famous controversy about the consciousness of thought processes. The controversy was never resolved and is in principle unresolvable within the introspective formulation. Introspectionistic views of consciousness have few advocates in mid-20th-century psychology.

Behaviourism in defining consciousness emphasizes its uniqueness as an aspect of human behaviour, which sets human behaviour apart from the behaviour of other organisms. Man is not merely capable of discriminative behaviour of a complex order; in addition he learns to respond discriminatively to his discriminative behaviour, for the most part in terms of the symbolic responses of language. Man is not only aware, he is aware that he is aware. He is said to be conscious in so far as his verbal behaviour indicates knowledge of his own awareness. Such knowledge of awareness exists in all degrees of reliability and validity as inferred from the consistency of relationships between verbal behaviour of subjective referent and larger patterns of conduct. We learn to discriminate aspects of the sensory awareness of vision and hearing more easily and reliably than the awareness from organic sensation; verbal responses regarding feelings and emotional experiences are generally vague and variable.

Nonetheless the definition of consciousness as awareness of awareness has merit with regard to problems of human psychology. Instances of disturbances of consciousness can be interpreted as discrepancies between awareness (discriminatory behaviour) and awareness of awareness (verbal responses). A hypnotic subject is given an illustrated magazine and told by the hypnotist that there are no women portrayed in the magazine, that the page has turned blank wherever a woman is pictured. The subject looks, and reports only men and things—and blank spaces. Yet clearly he must see the woman in order to report that he does not see her. He is aware, but not aware that he is aware.

Discussions of where in the hierarchy of animals or at what point in the development of a child consciousness first appears are clearly terminological. If awareness of the environment, indicated by discriminatory reactions, is the criterion of consciousness, then even the protozoans are conscious. If awareness of awareness is required, then it is doubtful whether the great apes and human infants are conscious.

**Neurophysiological Mechanisms.**—That consciousness depends on the function of the brain has been known from ancient times. Although detailed understanding of the neural mechanisms of consciousness has not been achieved, correlations between states of consciousness and functions of the brain are possible. Levels of consciousness in terms of levels of alertness or responsiveness are correlated with characteristic patterns of electrical activity of the brain (brain waves) recorded by the electroencephalograph from electrodes placed on the scalp (see ELECTROENCEPHALOGRAPHY). During wide awake consciousness the pattern of brain waves consists of rapid irregular waves of low amplitude or voltage. In contrast, during sleep, when consciousness can be said to be minimal, the brain waves are much slower and of greater amplitude, often coming in periodic bursts of slow waxing and waning amplitude. Intermediate levels of consciousness can often be related to intermediate patterns of brain waves. When electroencephalographic records are made continuously during normal sleep, occasional periods will be observed during which the brain waves approximate the waking pattern. If the person is awakened at such a time, he will almost always report that he was dreaming. On the other hand if he is awakened during a period of deep sleep as indicated by the brain waves pattern, he almost never reports a dream.

Both behavioural levels of consciousness and the correlated patterns of electrical activity are related to the function of a part of the brain located in the brain stem called the reticular formation (see also BRAIN). The reticular formation consists of a central core of gray matter extending from the medulla oblongata to the

upper end of the midbrain and, functionally at least, it may be said to extend on through the middle region (intralaminar) of the thalamus. The reticular formation is primarily neither motor nor sensory in function, but it does receive collateral fibres from the incoming sensory pathways, and nerve fibres extending from the reticular formation to the spinal cord conduct impulses which modify excitability of neurons in spinal reflex centres. There is also a diffuse projection system of fibres from the reticular formation to the cerebral cortex which conducts impulses modulating cortical functions related to consciousness. Electrical stimulation of the ascending reticular system from indwelling electrodes arouses a sleeping cat to alert consciousness and simultaneously activates its brain waves to the waking pattern.

Extensive development of the cortex of the cerebral hemispheres is the most notable feature observed when comparing the human brain with brains of animals lower in the phylogenetic scale. Consequently, it was commonly supposed that the neurophysiological mechanisms subserving consciousness and the higher mental processes must reside in the cortex. It is more likely that the cortex serves more specialized functions integrating patterns of sensory experience and organizing efferent motor patterns and that the ascending reticular system represents the neural structures most critically related to consciousness. Destruction of various parts of the cortex through accident, disease or surgical intervention may result in motor paralysis, loss of sensory capacity, decreased intellectual function or other symptoms, but consciousness itself is not markedly disturbed. Lesions in the upper brain stem reticular formation, on the other hand, are often associated with altered consciousness as evidenced by somnolence or coma.

The brain stem reticular formation should not be called the seat of consciousness. It represents an integrative focus, functioning through its widespread interconnections with the cortex and other regions of the brain. Animals from which all of the cortex has been excised show only limited responsiveness to the environment and thus can be called conscious at only a very low level. If the cortex of the human brain were destroyed, an even more profound loss of conscious responsiveness would undoubtedly result. Function of neurons of the ascending reticular system represents a necessary but not sufficient condition for conscious behaviour. See also PERCEPTION; UNCONSCIOUS.

**CONSCRIPTION.** The use of the word conscription to mean compulsory enrollment for military or naval service dates from the early 19th century. The word came into common usage in connection with the mass national armies employed by the French in the Napoleonic Wars, and by all the major belligerents in the Franco-German War of 1870 and in World Wars I and II. For the earlier history of the idea of national service, see the articles ARMY and MILITIA.

The French Revolution of 1789 saw the beginning of mass armies and of conscription, or compulsory national (military) service, as it is known today. After attempts to meet the country's needs by voluntary enlistment and by a levy had failed, the Directory in 1798 passed the first law of conscription requiring registration by classes of all able-bodied men between 20 and 25 for military service. Later this system enabled Napoleon, who extended it to include all able-bodied men, to enroll 2,613,000 conscripts between 1800 and 1813. This was an immense figure for those times, although it was to be dwarfed by the vast armies of World Wars I and II. (See FRANCE: Defense.)

In order to explain the working of conscription in the form it took in the 19th and early 20th centuries, it is necessary to go back to the battle of Jena in 1806. After this victory Napoleon restricted the size of the Prussian army and this gave birth to

the idea of using a small cadre of professional soldiers as a "sausage machine" to train batches of conscripts in a short time and pass them to the reserve. This method enabled Prussia, in a few years, to build up a large reserve of trained men without infringing the conditions restricting the size of the standing army. This was the system on which the continental powers based their armies in preparation for World War I—a comparatively small corps of professional officers, and a cadre of long-service noncommissioned officers and soldiers, who were responsible for operational and administrative staff work and for instructing the conscripts forming the bulk of the army—who served for one, two or three years as full-time soldiers before passing to the reserve. By this means France, Russia, Germany and Austria-Hungary were, in 1914, able to deploy large forces within a few days of mobilization and to follow these up quickly with reserve divisions composed of conscript reservists.

The armies recruited by conscription were mostly confined to the countries of continental Europe, up to World War I. The United States had no land frontiers liable to attack and maintained only a small professional army. The United Kingdom based its defense on its insular geographical position and on the Royal Navy. It had to provide garrisons for India and other overseas possessions, but these were small in numbers by continental standards and required long-service soldiers. The British Dominions had no threatened land frontiers and maintained only small regular forces. Even in the first decade of the 20th century, when Britain became associated with France in an *entente cordiale*, British commitments on the continent were so small, and so vague, that no attempts to increase the size of the army were made, although great improvements in organization took place (see GREAT BRITAIN AND NORTHERN IRELAND, UNITED KINGDOM OF: *Defense*).

**World War I.**—Since the days of Oliver Cromwell's major-generals the British people had resolutely opposed any form of compulsion for military service. It was therefore satisfactory for the British government when in 1914–15 the number of volunteer recruits for the armed services equaled, if they did not exceed, the numbers which could be properly trained and equipped. As the war progressed, however, and the casualty lists increased, it became apparent that the army could not be maintained at the required strength by voluntary enlistment. Moreover, Britain's allies became somewhat critical of its reluctance to adopt the compulsory measures which they had known for generations. There was another aspect to the problem which had been overlooked in the enthusiasm of the early months of war. Many key men in industry had joined the forces and their loss was detrimental to the production of munitions and other work indirectly connected with, but essential to, the prosecution of the war. It was clear that enrollment in the fighting services should be selective and based on methods that would result in men doing the jobs in which they would be most useful. This was possible only under conscription. It is, however, a measure of the British people's dislike of compulsory military service that it was not until Jan. 1916 (17 months after hostilities began) that conscription was introduced. With the end of the war in Nov. 1918 the British at once reverted to the voluntary system of enlistment and to an army of much the same size and pattern as in 1914. Germany was limited by the armistice terms to a long-service army of 100,000 men. The U.S.S.R., still suffering acutely from the effects of the revolution of 1917, continued conscription into the Red army, but it was loosely applied and for many years inoperative in the more remote provinces. France alone among the powers continued conscription on pre-1914 lines.

**World War II.**—By 1939 the pattern of war, and the equipment of the armed services, had undergone radical changes which had altered the conception of conscription: some acquaintance with these changes is necessary for a proper understanding of the problem. It was clear that war would require a combined effort by all three fighting services—on land, at sea and in the air. The recruitment of personnel for the service would affect all three and not be mainly an army problem. Within the services a high proportion of men would have to be skilled workers, with skills analogous to their trades in civil life, in order to operate and

maintain the tanks, aircraft, complicated warships, radio sets and other mechanical devices which science and the engineer had placed in the hands of commanders in all services. Moreover, the manufacture of these machines had assumed increasing importance and it was necessary that the armament firms—as well as other key undertakings such as coal mining, steelworks, farming and transport—should retain at least a proportion of their skilled workmen. The best military opinion, which proved to be correct, forecast that in contrast to World War I, the next war would be one of high mobility in which the air would play a great part. Machines would take the place of men to an increasing extent in battle, and a much higher standard of tactical and mechanical skill would be necessary. Under these conditions conscription had to be selective and applied in a highly scientific manner.

It was in these conditions that the Commonwealth of Nations, and the continental powers of Europe, in 1933 (when Adolf Hitler came into power in Germany) considered the problems of preparing for World War II. In France, Poland, the U.S.S.R. and Italy conscription already existed. Germany adopted compulsory service nominally when it repudiated the disarmament clauses of the Versailles treaty in 1935; but in practice it had evaded the restrictions on the size of its forces for some years before that. The first 18 months of hostilities demonstrated conclusively that the right kind of machines, properly handled by a few men, had largely taken the place of mass armies as the tactical means of victory. Poland was conquered in three weeks, France in 35 days and Greece in 18 days. In the winter of 1940–41 a small British force destroyed an Italian army of 220,000 men in two months in North Africa. In these decisive successes tanks and aircraft played the major part. It soon became clear, however, that large numbers of infantry, supported by artillery and engineers, were required to consolidate victory and occupy the vast areas overrun by the new mechanized formations.

To summarize, it can be said that in World War II, although machines conserved manpower on the battlefield, they increased the number of men required for supply and maintenance, and in the factories to produce the new equipment. The length of the war—nearly six years—and the vast areas of operations in all parts of the world, resulted in all belligerent countries, except the United States, suffering acute manpower shortages in the services and in the factories.

An interesting development in Great Britain in World War II was the introduction of conscription for younger women, who were liable to call-up from Dec. 1941 until Jan. 1947.

**Conscription after 1945.**—The era of freedom from the fear of war which had been expected after World War II did not come. Under the new grouping of east and west practically all the countries of Europe and the United States continued compulsory military service.

The emergency of a world war is sufficient to convince most people of the necessity for conscription; but this is not always possible in peace. Dictatorships have an advantage over democracies in this respect. In the former, conscription can be imposed under whatever conditions are considered best to meet military requirements. Compulsory service is never popular, however, in a democracy, and any party advocating it must convince the electors that conscription is a necessity in order to be sure of gaining power. There is therefore always a temptation for political parties to advocate the abolition of conscription, or some easement in the conditions of service, which is not justified on military grounds, but which may catch votes.

Conscription takes three forms: (1) Universal National Service, as in Great Britain, France and the U.S.S.R. in which all fit young men on reaching a given age, usually between 17 and 20, become eligible for a considerable period of full-time service, followed by a period of part-time service in a nonregular unit, or on the reserve. In Israel, unmarried women are also conscripted for military service on the same basis as men. (2) Selective National Service, as in the United States, where only a proportion of young men are drafted for full-time service, partly according to the needs of the armed services and partly according to their occupation, schooling, or family status. (See below, *The United*

States.) (3) Part-Time National Service, where most of a young man's service is part-time, as in Australia.

The following were the conditions for compulsory service in Great Britain and some other countries in the late 1950s.

**Great Britain.**—Under the National Service act of 1947-48 (as amended 1948-49, 1950 and 1955) Britain adopted universal military service for a full-time period of two years (except for a short time when it was reduced to 18 months) followed by three-and-a-half years in the territorial army or emergency reserve. Early in 1956 the system was altered by increasing the age of call-up, on a sliding-scale principle, so that by about March 1958 it would be at 19 instead of at 18 years of age. The two-year full-time period was retained, but the part-time period became only one year. In April 1957 plans were announced for ending compulsory national service by 1960. The age of call-up would continue to be raised gradually, to 20 or even 21. It was intended not to call up all those born between 1938 and 1940 who had registered for service, but they would remain legally liable.

An idea of the numbers affected by peacetime conscription can be gained from studying the figures for 1955. In this year 232,766 men registered for service, of whom 120,286 stated a preference for the army, 82,449 for the air force and 26,263 for the navy. Of the remaining 3,768, there were 733 (0.3%) accepted as conscientious objectors, and the remainder expressed no preference. The actual number called up was 156,833, the rest being either medically unfit or exempt for some special reason. They were allotted as follows: army, 108,656, air force 42,072, navy 6,105.

Contrary to the forebodings of many, peacetime national service in the British fighting services was successful. Many national service officers and men distinguished themselves in Korea, Malaya and other operational theatres in which the British army was involved after 1945.

**Other Countries.**—*France.*—Eighteen months' full-time service usually begins at the age of 20, followed by a period on the reserve.

*German Federal Republic.*—After the recognition of the sovereignty of the German Federal republic in May 1955, which carried with it the right to rearm, and the country's simultaneous entry into the North Atlantic Treaty organization and Western European union, which laid it under an obligation to provide forces for European defense, plans were made for the introduction of conscription. A bill was passed in 1956, despite considerable political opposition within the country, providing for compulsory military service for men between 18 and 45, for 18 months. The period was later reduced to 12 months.

*U.S.S.R.*—Compulsory service begins at the age of 16 when boys enroll as cadets. This is followed by full-time military service at the age of 18 or 19. The period of service is two years for privates and three for N.C.O.'s (army); four years for privates and N.C.O.'s in the air force or coast defense units; five years in the navy. These periods are followed by periods on the reserve up to the ages of 35, 45 and 50 according to physical fitness.

*Australia.*—Youths become eligible for national service on attaining the age of 18. They serve for 14 weeks full-time in their first year plus another two years part-time in the citizen military forces.

*New Zealand.*—Youths are called up at the ages of 18 for 10½ weeks training in their first year and 14 days camp and 6 other days training (during weekends) for the next two years. They then pass to the reserve for six years.

There is no form of compulsory military service in Canada, India or Pakistan.

## THE UNITED STATES

**Revolution and War of 1812.**—During the Revolution and the War of 1812 the volunteer system failed to procure the men required for military purposes. To stimulate voluntary enlistments, bounties of money, land and clothing were granted to recruits. Massachusetts and Virginia resorted to conscription in 1777. On Feb. 6, 1778, two-thirds of the authorized continental army being recruited, congress recommended that the other colonies follow the example set by Massachusetts and Virginia. The aid extended by France, however, averted the necessity for conscription. During the latter part of the War of 1812, when volunteers failed to fill the depleted ranks of the army, congress considered several methods of conscription, but none was adopted.

**Civil War.**—Conscription for military service in the United States during the Civil War embodied some of the worst rather than the best features of European practice. While the Confederacy had replaced volunteering by universal conscription as early as April 1862, the North deferred similar action until 1863. After the policy of obtaining recruits through calling up the militia and through volunteering had failed, congress passed the Enrollment bill (March 3, 1863). It was a measure designed less to channel the nation's manpower into the armies than to stimulate volunteering. Applied only in areas which had not produced their quota of volunteers, it led to so-called draft riots and armed resistance against federal registrars.

Both northern and southern conscription included features of class legislation. In the North a drafted man could hire a substitute or buy exemption for \$300. Substitute brokers brought much corruption into the application of the draft, tending to strengthen popular belief that the conflict raging was "a rich man's war and a poor man's fight." The Confederacy shared this hiring of substitutes for a time and by such exemptions as that of owners of 20 (later 15) slaves, who were declared vitally necessary in their supervisory function, helped to break the unity of interest and feeling on which its strength was based.

In the North the draft was almost exclusively applied by federal authorities, such as the hated federal registrars. 98 of whom were killed as victims of popular wrath during the first four months of the application of the law; this unpopularity was increased by their simultaneous task of apprehending deserters and spies whose odium the draftees shared to some extent. The results of the draft were disappointing: while 1,120,000 were said to have been drafted, a mere 42,000 were actually inducted.

The lessons drawn from these experiences were impressive, if mostly negative. In subsequent applications of the draft in the United States, federal interference was kept at a minimum; conscription was introduced at or before the beginning of war without waiting for results from volunteering; bounties and purchasing of substitutes were prohibited; and the hunt for spies and deserters was separated from the task of draft authorities and left to federal police.

**World War I.**—Shortly after the start of World War I, congress passed the Selective Service act of May 18, 1917. To procure the necessary military and naval manpower and still not deplete the nation's war-productive forces, the law provided that the whole adult male population of the land, only enemy aliens excluded, between the ages of 21 and 30 inclusive (later extended to include the 18-to-45 group), were made a reservoir from which to draw recruits by lot. Altogether, 24,000,000 were registered by the end of the war.

Of these, 2,810,296 men were inducted through selective service, beginning in Sept. 1917, while the total military forces raised between April 1, 1917, and Nov. 11, 1918, amounted to 3,891,540 men; approximately 1,000,000 had enlisted voluntarily in the army. To obtain the total of the armed forces of the U.S. the 605,952 men in the navy and marine corps, most of them volunteers, must be added. These numbers point to the undoubted fact, as Gen. Enoch H. Crowder, the chief draft executive, put it

that "recruiting played havoc for a time with the orderly process of selection. . . . The volunteer plan took no heed of economic value; it received as readily the men indispensable to production as it did the industrially worthless." To obtain a better division of manpower, a presidential order of July 27, 1918, forbade further enlistments by the navy or marine corps of Class I registrants, men immediately liable to call; later all recruiting by navy or army was suspended.

The act provided for a number of exemptions, some mandatory and others at the discretion of the president. The former group included the legislative, executive and judicial officers of the union and the several states, territories, etc.; ordained ministers, theological students preparing for the ministry, and conscientious objectors, these to be exempt from combat duties. As regards the group of exemptions at the discretion of the president, he was authorized to exempt persons of the following groups: county, municipal, customs-service, mail officials; workmen in armouries, arsenals, etc.; merchant mariners in actual employ; "persons engaged in industries, including agriculture, found to be necessary to the maintenance of the military establishment or the effective operation of the military forces or the maintenance of the national interest during the emergency"; persons with obligations toward dependents which made their exemption or discharge advisable; persons physically or morally unfit.

The president was empowered to draw upon the services of agents and officers of the state governments, and most of the administration of the act was through state executives, 155 district and 4,648 local selection boards, with the main burden of work and decision falling on the latter. These consisted of three members (usually including a physician) all of whom were civilians and residents of the districts where they served, appointed by the president upon recommendation by the state governor. They processed registrants under a fixed procedure for hearing and resolving claims for exemption and deferment and taking into account the results of physical examination. Eventually they arranged available manpower in four classes in accordance with industrial usefulness, liability toward dependents, etc., with the first class containing those most readily called and whose withdrawal was least likely to upset war-essential industry and the family structure of the nation; in Classes II to IV registrants were graded in order of availability for the armed service; the exempt were placed in a fifth group. This classification resulted in the following distribution:

Total registrants classified after Dec. 15, 1917.....	9,952,735
Placed in Class I .....	2,979,465
"    "    "    II .....	989,568
"    "    "    III .....	407,125
"    "    "    IV .....	3,026,178
"    "    "    V .....	2,123,825
Undistributed .....	426,574

Altogether 65% of the total registrants were exempt or given a deferred status, with dependency accepted as the chief reason. To determine the order for calling up selectees and at the same time exclude possible local fraud or favoritism, a central lottery in Washington, D.C., was used to fix from time to time the call numbers of registrants. The first of these drawings took place on July 20, 1917.

None of the earlier conscription laws and practices included attempts to provide effective disposal of manpower for the purposes of war in all its sectors. This feature was introduced by the industrial demands of World War I. Selective service, after filling the cadres of the armies, had to channel a necessary part of available manpower, fortunately ample, into war industries, which doubtless attracted numbers of unsuitable workers eager "to get out of the draft." Aside from the silent pressure exerted by the act, a "work or fight" order, issued May 17, 1918, was aimed at employees, of deferred status, in certain nonessential occupations, such as sales clerks, waiters, doormen and domestics. By this order deferred registrants in Classes I to IV who were idle or in nonessential jobs were threatened with loss of preferred status unless they found war-essential employment.

The so-called Stone amendment of June 15, 1917, provided that

all men serving under the Selective Service act were to be discharged within four months after conclusion of peace; the act itself made enlistments in the regular army and the federalized national guard expire on the termination of the emergency.

**World War II.**—The National Defense act of 1920 provided for a possible return to conscription in an emergency by making it the duty of the war department general staff to prepare plans for mobilization. The research and planning undertaken by a joint army and navy selective-service committee, getting under way in 1926, were embodied substantially in the Selective Training and Service act of 1940. It was the first conscription law accepted by the United States in time of peace, ahead of war.

The senate voted for the bill 47 to 25 and the house 232 to 124. On Sept. 16, Pres. Franklin D. Roosevelt signed it—and by proclamation called upon all males from 21 through 35 years of age, residing in the U.S. and its territories, to register on Oct. 16 for selective compulsory military training. The act was to become inoperative on and after May 15, 1946, unless continued by congress. The president could not induct more men than congress should specifically appropriate from time to time. Not more than 900,000 men were to be in training at one time. They were to serve and be trained for 12 months, unless congress declared a national emergency keeping them with the colours for longer periods, after which they were to retire to a reserve component of the army or navy for ten years. This compulsory transfer to a reserve, a new feature in U.S. military legislation, was not enforced, however.

The Service Extension act of Aug. 18, 1941, declared the national interest imperiled and authorized extension of the training-service period to as much as 18 months. Men inducted were not to be employed beyond the limits of the western hemisphere and the U.S. possessions including the Philippines, a limitation removed Dec. 1941, following entry of the U.S. into the war.

Many features of the 1940 act were in substance taken over from the 1917 act. An entirely new principle was directed at job insurance for the inducted men, provisions requiring employers, private or public, under certain conditions to reinstate the returning serviceman in his former or a similar position without loss of rank, seniority or reduction in pay. Administration of the draft, though somewhat more strongly centralized than it had been during World War I, closely resembled that of 1917–18 in most respects, as in the use of state and local government agencies, or the exclusive use of civilians in local boards.

Eventually, the Selective Service system included a headquarters in each state, 6,443 local boards, one for each area of about 30,000 inhabitants, and 505 appeal boards; the latter were to have jurisdiction over a territory with about 70,000 registrants as the result of the first registration. The national organization was headed by a director of selective service, with Clarence A. Dykstra, appointed Oct. 15, 1940, the first incumbent. Dykstra was succeeded by his deputy, Brig. Gen. Lewis B. Hershey, on July 31, 1941.

**Registration.**—On Oct. 16, 1940, and later days in the territories, 16,632,146 men were registered in about 125,000 registration places. Six subsequent registrations under the act as amended were held in 1941 and 1942. After that men were required to register with their local board on attaining their 18th birthday. As during World War I, the cards of registration were forwarded to the local Selective Service boards for processing, including serial numbering, to be used in the national lottery. The first lottery to determine the order numbers for induction was held in Washington on Oct. 29, 1940.

To all registrants, in the sequence of their order numbers, the local boards then sent a questionnaire, and on the basis of information elicited, and of medical examinations, began to classify each registrant according to availability and fitness. Class I comprised men available for military duty, with Class I-A containing those fit for general duty, I-B those fit for limited service only and I-C those actually in the armed services. In Class II were put men necessary to the war work in their civilian capacity, in Class III men with dependents, and in Class IV officials deferred by law, nondeclarant aliens, ministers and divinity students, conscientious

objectors and those physically, mentally, morally unfit. Appeal was open to every registrant as well as to government appeal agents, and also to other parties interested, such as an employer or a dependent. No appeal against the medical classification, however, was admitted.

Those found physically, mentally or morally unfit for service, and therefore rejected and put in Class IV-F, varied from 31.4% for Jan. 1943 to 46.9% for Dec. 1943.

Classification was followed by selection and induction. The first call for men was issued early in Nov. 1940 and comprised a mere 19,670 of the 800,000 who were to be inducted through Selective Service by July 1, 1941. The numbers required by the armed services were prorated among the states.

With the declaration of war against the Axis powers, new and vaster demands upon U.S. manpower arose. Legislation removed remaining restrictions and prolonged the service period to the duration of the war plus six months. The ages of registration were extended to include ages 18 to 65, though only the 20-to-45-year groups were at the time made liable to service. The existing board system was found elastic enough to cope with increased demands for manpower raised by the armed forces on the one hand, whose monthly calls rose from 99,929 in Jan. 1942 to 450,000 in Dec. 1942, and by war industries and agriculture on the other. However, a more complete and central direction seemed needed; for one year, from Dec. 1942 to Dec. 1943, the all-inclusive administration through the War Manpower commission was made to include the Selective Service system, which was then returned to its independent status. As in World War I, it was found necessary to end voluntary enlistment, at least for persons 18 to 38 (executive order of Dec. 5, 1942), for both services. Registrants with a dependency status were notified early in 1943 that they would lose deferment unless they changed to war-essential work from about 20 occupations defined as nonessential. To provide for dependents of inducted breadwinners congress passed the Servicemen's Dependence Allowance act of 1942 and the Pay Allowance act.

Not long before V-E day, on March 1, 1945, the status of United States manpower under Selective Service was as follows: of the 22,085,000 registrants, 18 through 37 years old, nearly 50% had been inducted or had enlisted, while 25% were disqualified because of physical disability, extreme hardship to dependents or statutory exemption. Of the remaining 25% more than four-fifths were deferred because of essential occupations and about one-sixth were in the I-A class, available at the time for immediate induction.

**After World War II.**—After much debate, congress passed and Pres. Harry S. Truman signed on May 14, 1946, a measure to extend the existing draft law until July 1. Induction of fathers and of youths 18 and 19 years old was stopped at the same time. On June 25, 1946, congress extended the Selective Training and Service act of 1940 to July 1, 1947, and Selective Service itself to March 31, 1947. This legislation marked the first postwar extension of the principle of conscription in United States history. The amended law exempted the 18-year-old group from the draft. Beginning Oct. 1, 1946, all inducted men were to serve for a training and service period of 18 consecutive months.

Congress ended the Selective Training and Service act of 1940 on March 31, 1947, but provided for the continuance of a skeleton organization in the Office of Selective Service Records. The following year, congress passed the Selective Service act of 1948, the nation's second peacetime draft law, to run for two years. The act required all male residents between 18 and 26 years of age to register on dates fixed by the president; exemptions were few. The period of service was to be 21 months, followed by a maximal 5 years' membership in the reserve. The act allowed a maximum number of 161,000 men of 18 to enlist for one year on condition of a subsequent membership for six years in the reserve during which they might be called up for training periods not exceeding 30 days annually. The exemptions covered most veterans of World War II, though not wartime members of the merchant marine. Deferments were provided for members of the reserve and of the R.O.T.C., public officials during their term of office,

married men and men with dependents, high school and college students.

Calls for induction, beginning with the 25-year group, were issued by the armed forces in Sept. 1948, and the first groups were inducted in Nov. 1948. Because of the subsequent increase in voluntary enlistments, however, no one was inducted after Jan. 1949 and most inductees were released. In Aug. 1949 congress reduced the Selective Service system to a skeleton organization. By Feb. 1950, all those inducted under Selective Service had been released and the U.S. armed forces were once again on an all-volunteer basis of recruiting.

**Korean War.**—After the start of the Korean War in June 1950, the Selective Service act of 1948 appeared inadequate to bring the armed forces up to the required level of 3,300,000. It was amended in September 1950 by the so-called "doctor draft" to help meet the needs of the armed services for doctors, dentists, and allied specialists. In June 1951, the Universal Military Training and Service act was enacted. This law lengthened the required term of service from 21 to 24 months; reduced the minimum age of liability for service from 19 to 18½; reclassified registrants deferred for dependency whose only dependents were wives; reduced the mental standards for service; continued until age 35 liability for service for most deferred registrants; and expanded the use of conscientious objectors in civilian work.

From June 1950 until the Korean armistice in July 1953, annual requirements for the armed forces exceeded 1,000,000 men. Inductions averaged 45,000 a month. This volume of inductions, plus the large number of men who enlisted, and the high rejection rate, caused the supply of registrants available for military service to decline from 3,000,000 in June 1950 to 1,000,000 in June 1953.

**Reserve Forces Act.**—With the immediate demands of the Korean War ended, the department of defense and congressional leaders discussed means of improving the utilization of military manpower. After nearly two years of discussion, the Reserve Forces act of 1955 was passed. One of its main purposes was to strengthen the nation's reserve forces. The new law liberalized the alternatives available to young men in fulfilling their military obligations and permitted properly qualified men to defer training until completing their education. Its basic requirement was six years of military duty, counting both active and reserve duty. When a young man was drafted, or enlisted in a branch of his own choice, he might serve from two to five years on active duty, followed by further service in the ready reserve or stand-by reserve. If, for example, he served for two years on active duty he would be obligated to spend two years in the ready reserve followed by two years in the stand-by reserve for a total of six years.

The ready reserve consisted of organized and trained individuals and units, including the national guard and the air national guard; they were normally subject to 48 weekly drills and a maximum of 17 days active duty annually. Members of the ready reserve were also subject to call to immediate active duty whenever the President declared a national emergency. The stand-by reserve consisted of men not in organized units. Such men were subject to call to active duty only upon the authority of congress and only after the Selective Service system had determined on an individual case basis whether they were available for call.

The act also offered short-term alternatives to active duty. Draft-eligible young men, before reaching the age of 18½, might enlist in the national guard or volunteer for six months of active duty. Those who chose the six months of active duty were after completion of their tours, placed in the ready reserve for three years and the stand-by reserve for four and one-half years. Those who chose the national guard might be required to attend weekly drills and summer encampments until the age of 28. This service could be reduced to eight years at any time if the individual volunteered for three to six months of active duty. Beginning in the fall of 1957, men with no prior military service who enlisted in the national guard were required to take a minimum of six months of active duty training in a federal status. Those enlisting in the air national guard were required to take a minimum of 11 weeks of basic training with the active air force.

Men with critical skills, such as geologists and engineers, of

men employed in vital industries, could apply for a special training program that permitted three to six months of active duty training, followed by seven and one-half years in the stand-by reserve.

Anyone in the ready reserve might be placed in the stand-by reserve if his work was of such a vital nature as to make it probable that he would not be available for military service at the time of mobilization.

**CONSECRATION** is an act by which a person or a thing is separated from secular or profane use and dedicated permanently to the service of God by prayers, rites and ceremonies. Consecration is distinguished from blessing, or benediction, and from dedication in that consecration effects an intimate transformation in the essence of the object, and that it is permanent and can be neither revoked nor repeated. The Roman pontifical treats of the consecration of a bishop, of a fixed altar, of an altar stone, of a church and of a chalice and paten. The ordinary minister of a consecration is a bishop, and the ordinary minister of a blessing is a priest. At a consecration, holy oils are used; at blessings, customarily holy water.

In the Old Testament, which has served as the basis for many kinds of consecrations in Christianity, among the persons consecrated were priests (Ex. xxix), kings (I Sam. [I Kings] x, 1) and prophets (I Chron. [I Paralipomenon] xvi, 22). Among things consecrated may be mentioned the pillar or stone of Bethel (Gen. xxviii, 18), vessels of the Tabernacle (Lev. viii, 10-11), the altar of holocausts (Ex. xxix, 36) and the second Temple (Ezra [I Esdras] vi, 16-17), which is commemorated at Hanukkah, the Feast of Dedication.

**Consecration of the Eucharist.**—In the Roman Catholic Church the word is used in a special sense to signify what takes place when the words of Jesus Christ at the Last Supper are pronounced during the Mass: "This is my body"; "This is the chalice of my blood." These words are repeated at the altar in the name and in the person of Jesus Christ. The substances of bread and wine then become the body and blood of Christ, only the appearance of bread and wine remaining (as defined by the Council of Trent; see **TRANSUBSTANTIATION**). Jesus Christ is here regarded, at one and the same time, as both the priest and the victim of the eucharistic sacrifice.

The Orthodox Churches and Eastern Rites of the Roman Catholic Church use a distinct invocation of the Holy Spirit after the words of consecration. Some Orthodox scholars consider this invocation or epiclesis essential for the consecration; other Orthodox authorities and the Eastern Rites of the Roman Catholic Church do not.

In the Anglican liturgy, generally, the prayer of consecration merely sets apart for sacred use the bread and wine, no substantial change taking place: they do not become the body and blood of Christ. Some Protestants hold that the only effective consecration is the original words of the Last Supper, and that they included potentially every subsequent celebration of the Eucharist.

**Consecration of Bishops.**—From the earliest times, the discipline of the church ordered that there be at least three bishops for the consecration of a new bishop. The consecration takes place by the imposition of hands, as mentioned in the New Testament (Acts xiii, 3; II Tim. i, 6).

In all ancient liturgies, Syriac, Maronite and Coptic, the theme is the same: along with the imposition of hands, prayer is offered to the Holy Spirit that he may make the candidate worthy of his

office as priest and pastor in the sacrifice of prayer and the Eucharist, the conferring of orders and other episcopal prerogatives. There is also an anointing with chrism (*q.v.*). Those Orthodox rites which omit the unction make a triple sign of the cross on the head or on the forehead to remind the candidate that he must bear the image of Christ. All the rites, Latin, Greek and Syriac, include the imposing of the Gospels on the neck and shoulders of the elect. The ring and crosier are also given as a mark of the office.

The Roman Catholic ceremony of episcopal consecration begins with the reading of authorization for the ceremony, the mandate of the pope, to whom the bishop-elect pledges loyalty. In the Anglican ceremony, a combination of religious and civil ceremonies, the royal mandate for the consecration is read and the oath touching the acknowledgment of the royal supremacy is taken by the bishop-elect.

**Consecration of a King.**—The anointing of kings antedates Christianity. Christian records reveal the most ancient of these ceremonies occurred in Gaul. Theodosius II, who died in A.D. 450, was consecrated king by the patriarch of Constantinople, and Pepin and his two sons were anointed kings by Pope Stephen II (III). (See further **CORONATION**.)

**Consecration of Churches and Synagogues.**—From antiquity, church law required that a new church be solemnly consecrated, or at least dedicated to God by a blessing, before divine services could be held. In Judaism, a formal consecration ceremony takes place patterned after the traditional dedication ceremony of Solomon's Temple. The doors are formally opened during the reading of certain psalms. The perpetual light is then kindled and the scrolls of the Torah are put in their place. In the United States the tendency is to centre these dedication ceremonies about the sabbath service. In Protestant churches the dedication consists in reading from Scripture, prayers and sometimes anointing. Consecration of a Roman Catholic church includes anointing the walls with chrism, the places of anointings being indicated by 12 crosses.

**BIBLIOGRAPHY.**—J. A. Abbo and J. D. Hannan, *Sacred Canons*, 2 vol. (1952); A. Baumstark, *Comparative Liturgy* (1958); R. W. Muncey, *A History of the Consecration of Churches and Churchyards* (1930). (F. J. SR.)

**CONSEQUENS**, a Latin word meaning "consequent" or "following," used in traditional logic to designate that part of a hypothetical proposition which states the result or consequence of the condition or antecedent (*antecedens*, "preceding"). Thus the general form of such a proposition can be expressed as "If A, then C" ("If the *antecedens*, then the *consequens*"); e.g., "If it rains, then the streets are wet." If a given hypothetical proposition is sound, then the fulfillment of the condition specified in its *antecedens* entails the result specified in its *consequens*, but the realization of the phenomenon specified in the *consequens* does not conversely entitle one to conclude that the *antecedens* has been fulfilled. To do so is to fall into the "fallacy of *consequens*." Thus, on the basis of the proposition already cited, when it is raining one may logically expect the streets to be wet; but when the streets are found to be wet the proposition by itself does not logically justify the assumption that it must have been raining.

**CONSERVATION:** see **NATIONAL PARKS AND NATURE RESERVES**; **NATURAL RESOURCES**, **LAWS CONCERNING (U.S.)**; **WILDLIFE CONSERVATION**.

**CONSERVATISM**, a term commonly used in politics to denote a preference for the old and tried in the civil social order rather than for the new and untried. The word was first used to describe certain political beliefs and practical measures adopted in France during the era that followed the fall of Napoleon. From France it spread in the 1820s and 1830s throughout western Europe, to England, and by the 1840s had reached the United States.

As a coherent body of ideas about politics, conservatism is a modern attitude or movement. It is about as old as the different body of ideas called liberalism, and some decades older than the

ideologies called socialism, communism and anarchism. The roots of conservative thought, nevertheless, extend deep into the history of ideas and of social institutions. The title of "conservator" was given in various medieval states to guardians of the laws or guardians of particular groups. English justices of the peace originally were styled *custodes pacis*—conservators of the peace. Thus when French politicians and writers were seeking for some name to describe their movement toward a social order which would reconcile the best in the old Europe with the necessities of the 19th century, they hit upon the concept of the *conservateur*, the guardian of the heritage of civilization and of the principles of justice. The word conservative was popularized in England by George Canning and the *Quarterly Review* in the 1820s, and entered American usage only some years later when John C. Calhoun and Orestes A. Brownson began to employ it.

Though Edmund Burke's writings furnished both continental and English-speaking conservatives with their principal theories, Burke himself did not employ the word "conservative." Because Burke's thought and career also influenced 19th-century liberalism, there at first existed no sharp demarcation between the terms "conservative" and "liberal"; in France, philosophical statesmen as varied in opinion as Chateaubriand, Guizot and Tocqueville often were called—and called themselves—both conservative and liberal. But the revolutionary movements of 1829–30 and of 1848 established better-marked party lines, emphasizing the differences among conservatives, liberals and radicals. Throughout Europe "conservatism" came to mean hostility toward the principles of the French Revolution, with its violent leveling innovations, while "liberalism" implied sympathy with the revolutionary concepts of liberty, equality, fraternity and progress. In the sardonic definition of Ambrose Bierce (see his *Devil's Dictionary*), a conservative is "a statesman enamored of old evils, as contrasted with the liberal, who would replace them with others."

**First Principles.**—Conservatism is not, strictly speaking, a political system but rather a way of looking at the civil social order. Although certain general principles held by most conservatives may be described, there exists great variety from nation to nation and from age to age in the application of these doctrines. Thus conservative views and parties exist under monarchical, aristocratic and democratic regimes, and in a considerable range of economic systems. The conservatives of Peru, for instance, differ greatly from those of Australia; they may share a preference for the established order but the institutions and customs they desire to preserve are not identical.

Unlike socialism, anarchism or even liberalism, then, conservatism offers no universal pattern of politics for adoption everywhere. On the contrary, conservatives maintain that social institutions must always differ from nation to nation, since any country's politics in large part must be the product of that country's historical experience, dominant religion and ancient habits. Conservatism, in brief, is a body of convictions but not an ideology; it does not advocate a simple, universal program for establishing a perfect social order.

Though it is not an ideology, conservatism may be defined reasonably well by listing a number of basic opinions that most eminent conservatives have shared. The following first principles are best discerned in the theoretical and practical politics of British and U.S. conservatives, but apply in considerable degree to western conservatism generally, and even to those Asian and African states that adopted European vocabularies and approaches in politics.

1. *The principle of natural law.* Most conservatives have held, with Plato and Cicero, that there exists a natural law, of an origin more than human, to which any society ought to conform. The object of the political philosopher is to ascertain as best he can this norm of justice, of which man-made law is at best a bad copy. A divine intent, however dimly discerned, is at work in men's lives and in their society. This point of view contrasts strongly with the liberal's utilitarian view of the state (most consistently expressed by Jeremy Bentham) and with the radical's detestation of theological politics. Modern conservatives

seek to maintain a society in which each man receives the things that are suited to his nature; social equality and uniformity, conservatives think, are contrary to the real nature of man and are basically unjust.

2. *The principle of continuity.* "When it is not necessary to change, it is necessary not to change," Lord Falkland said during the English Civil Wars. This is an axiom among conservatives, who generally prefer the devil they know to the devil they do not know. Order and justice and freedom, the conservative feels, are the artificial products of a very long and painful human experience, the products of many centuries of trial and error and reflection. Human society is a kind of spiritual corporation, like the church; or, as some 19th-century conservatives maintained, it is an organic growth like a tree. Certainly human society is not a machine and cannot be treated mechanically. It is of the first importance that the continuity, the lifeblood, of a society must not be interrupted. Radical reformers, in George Santayana's phrase, never know how close to the root of the tree they are hewing. As the human body casts off old tissue and takes on new, so human society, too, must alter. Burke's model of a statesman was one who combined a disposition to preserve with an ability to reform. But necessary change ought to be gradual and reluctantly undertaken, lest the delicate constitution of any society, the essential continuity of human relationships, be badly disturbed.

3. *The principle of prescription.* "The wisdom of our ancestors" is one of the most important phrases in the writings of Burke, who found it, perhaps, in the pages of Richard Hooker. With Fulbert of Chartres, conservatives feel that modern men are dwarfs on the shoulders of giants, able to see further than their ancestors only because of their ancestors' high stature. Thus the conservative emphasizes the importance of what Burke called "prescription"—ancient rights, moral precepts and customs. Conservatives argue that men are unlikely to make any great new discoveries in morals or politics or taste. Society is more secure when its members are accustomed to refer to inherited wisdom, the legacy of civilization, rather than to weigh every ephemeral issue on the basis of private judgments and private rationality. "The individual is foolish, but the species is wise," Burke declared. In politics, we will do well to refer often to precedent and precept and even prejudice, for "the great mysterious incorporation of the human race" has learned truths about the soul and about community living that no single man can hope to attain unaided in his few brief years of life.

4. *The principle of prudence.* Any measure ought to be judged by its probable long-run consequences, not merely by temporary advantage or popularity: this is the real statesman's art, according to the conservative. Liberals and radicals, the conservative thinks, are imprudent, for they dash at their objectives without considering that their reforms may bring in their train abuses worse than the evils that reformers aspire to abolish. Human society being complex, remedies cannot be simple if they are to be effective. The conservative declares that he acts only upon due reflection and after weighing the consequences; sudden and slashing reforms are as perilous as sudden and slashing surgery.

5. *The principle of variety.* The philosophic conservative feels affection for the proliferating variety and intricacy and mystery of long-established social institutions and modes of life, as distinguished from the narrowing uniformity and deadening egalitarianism of most radical systems. For the preservation of a healthy diversity in any civilization, there must be various orders and classes, differences in economic condition and many kinds of inequality. The only true equality is equality before God's judgment; all other attempts at leveling lead to stagnation, at best. Society longs for able leadership, and if natural and institutional distinctions among men are destroyed, presently some tyrant fills the vacuum. Similarly, the conservative upholds the institution of private property as productive of human variety; without private property, liberty is almost impossible and society becomes a life-in-death.

6. *The principle of imperfectibility.* Human nature, the conservative is convinced, suffers irremediably from certain great

laws or faults, which the Christian calls original sin. Men being imperfect, no perfect social order ever can be created. Because of man's native restlessness, indeed, mankind would grow restive under any utopian domination and once more break out in violent discontent—or else expire of boredom.

To aim for utopia is to end in disaster, the conservative reasons: we are not made for perfect things. All that we reasonably can expect is a tolerably ordered, free and just society, in which there must always be some evils and maladjustments and suffering. By proper attention to prescription and prudence, we may hope to preserve and even to improve this tolerable order. But if the old institutional and moral safeguards of a nation are forgotten in an impatient snatch at perfection, then the anarchic and violent impulses in man break loose, and the fabric of a high civilization is in imminent peril.

Such are the major premises of what Walter Bagehot called "reflective conservatism." This conservative social theory found its first systematic spokesman in Burke and was added to by a series of men of intellectual power. Friedrich Gentz spread these ideas in German-speaking lands, Juan Donoso Cortes in Spain. Reflective conservatism continued to find its literary and philosophical champions most influential in England, however, with Walter Scott, S. T. Coleridge, John Henry Newman, Benjamin Disraeli, J. F. Stephen, W. E. H. Lecky, Henry Maine, W. H. Mallock, Arthur Balfour, T. S. Eliot, and many other conservative writers. In the United States, for a long while, a comparative immunity to European social conflicts and the process of westward expansion allowed the expression of conservatism—as of liberalism—to remain somewhat amorphous. The federal constitution and the early state constitutions, nevertheless, were successful expressions of conservative minds. Among the more eminent American conservative thinkers were John Adams, John Quincy Adams, John Marshall, John C. Calhoun, Orestes A. Brownson, John Randolph, James Fenimore Cooper, Nathaniel Hawthorne, James Russell Lowell, Henry Adams (with partial exceptions), Irving Babbitt, P. E. More and George Santayana.

**Popular Conservatism.**—Popular journalists often use the word "conservative" in a sense somewhat different from the intellectual conservatism described above. Among many people unfamiliar with the works of Burke or the Adamsses there exists a body of opinion which Walter Bagehot once unflatteringly described as "the ignorant Democratic Conservatism of the masses." This also has been called "shop-and-till conservatism," or mere attachment to things established, out of fear that radical political measures would injure or destroy the material interests of anyone possessing property. This "party of order," as it was called in France and elsewhere in Europe about the middle of the 19th century, is animated by fear, Bagehot wrote—"dread that their shop, their house, their life—not so much their physical life as their whole mode and sources of existence—will be destroyed and cast away." The French Revolution—and later, the Russian Revolution and other 20th-century upheavals—produced among middle-class people especially a reaction against violent and abstract innovation that greatly increased the popular strength of conservatism.

Of such a character was the conservatism of the *juste-milieu* during the reign of Louis Philippe in France. The middle-of-the-road course declared by the Eisenhower administration in the United States nearly a century later also displayed characteristics of this sort of conservative polity. Because such political administrations dislike extremes and endeavour to steer a course between reaction and radicalism, the word "conservative" has acquired a popular meaning of compromise and of search for some political golden mean. A desire for reasonable conciliation and a distrust of extreme measures have indeed been characteristic of conservatism. Yet it does not necessarily follow that conservative statesmen always must pursue a middle path: moderation scarcely was dominant in Burke, nor in such conservative American leaders as John Randolph or Theodore Roosevelt.

As socialists have tended to draw their votes from the labouring classes, so conservatives have tended to find strong support among the modern middle classes. But it is not easy to show a

close correspondence between political conservatism and personal prosperity. At times the Conservative party in Britain has won the votes of several million trade-union members, and millions of hard-pressed small farmers in the United States generally are conservative in their voting. That rural populations tend to be relatively conservative is less difficult to prove.

Conservative movements also have tended to attract persons of strong religious feelings, particularly during the reaction against the "age of reason" of the French revolutionaries, and in the 20th century as the Communist, Nazi and other collectivist ideologies displayed a character unmistakably antireligious.

During placid times, popular conservatism often lapses into complacency or apathy, only to revive suddenly when the mass of men is confronted by some tremendous threat to old ways of life. As F. J. C. Hearnshaw observes, "It is commonly sufficient for practical purposes if conservatives, without saying anything, just sit and think, or even if they merely sit." After 1914, however, mere inertia rarely sufficed to maintain prescription and tradition; and after the end of World War II a reasoned conservatism made some headway in a popular sense.

**Conservative Parties and Factions.**—Under various names, political parties founded on conservative concepts appeared throughout most of Europe at the beginning of the 19th century. In France, these organizations often were closely associated with the clergy, military officers and landed proprietors; they also enjoyed a good deal of support from peasants and from part of the middle classes. In northern Europe these parties were sustained principally by the landed gentry; in the Austrian system and in southern Europe, loyalty to the monarch and to the Roman Catholic Church was their rallying point. In the face of liberal organizations and revolts, the conservatives gradually lost ground; and after the revolutions of 1848, with the flight of Metternich from Austria and of Louis Philippe from France, conservative factions either lost power to nationalists and liberals or clung to influence only in coalition with other groups.

The coming of modern industrialism, too, hastened the decline of old-style conservatism, transferring wealth and power to new hands and breaking the "cake of custom." It undermined the habitual acceptance of things established, which is bound up with conservative doctrines of community, authority, prescription and tradition. Between 1830 and 1880, roughly speaking, liberalism won repeated victories over the conservative order.

Only in Britain did a party avowedly conservative retain great power throughout the 19th century, receiving the support of about half the electorate. Originally taking form as a coalition of Tories and Portland Whigs during William Pitt's war ministry, the English conservatives began to use the label Conservative in 1831 and 1832. Though shaken by the Whig Reform bill of 1832 and by the passage of other Whig and Liberal measures that undermined the power of the agricultural interest, they were rescued by the fertile imagination and astute management of Benjamin Disraeli. At the end of the century they stood seemingly at the summit of their popularity. The overwhelming Liberal victory in the general election of 1906 terminated this ascendancy—but only temporarily, for the rise of socialism was pressing the Liberals hard, and the Labour victory of 1924 meant the end of the Liberal party as an effective force. During the next four decades the Conservatives formed the government most of the time. In part, the success of the British Conservatives—now the oldest political party in the world—was a result of its having absorbed large successive segments of the old Liberal supporters, beginning in 1886. With these accessions came also some elements of Liberal policy, so that the Conservative party became a union of old Tory and Liberal factions, combined against Labour. (See also LIBERAL PARTY [BRITISH].)

In the English-speaking dominions conservative parties enjoyed a surprising revival late in the 1950s, after being eclipsed for nearly three decades: conservatives, or coalitions with policies substantially conservative, took office in Canada, Australia and New Zealand.

**Modern European Conservatism.**—After suffering suppression and other persecution under the dictatorial regimes of the

1930s and during World War II, European conservative groups began to regain vitality about 1946. Soviet power had extirpated effectual conservatism in Poland, Hungary, Czechoslovakia, Yugoslavia, Rumania, Bulgaria and lesser states; but to the chagrin of the western European socialists, conservative parties—or, more commonly, Christian Democratic parties in which various conservative and liberal elements were leagued—won national elections in several countries. By the 1960s conservative or quasi-conservative governments prevailed in the republics of France and West Germany, and in the Netherlands, Greece and elsewhere. In Italy and Austria, Christian Democratic politicians held office in coalition with socialists and smaller parties. In the Spanish and Portuguese dictatorships, conservative groups like the Spanish Tradicionalistas exerted a moderating influence. Socialism retained a secure hold only in Scandinavia.

This revived conservatism, however, was shorn of many of its old aristocratic associations and had come to terms, in most countries, with old-fashioned economic liberalism. Paradoxically, the conservatives' success was produced by the menace of Communism: after the failure of the Nazi and Fascist regimes, and the ineffectuality of postwar socialism, many Europeans turned once more to conservative policies as the only discernible alternative to a totalitarian order. Of these national governments, in some respects the most clearly conservative was that of General de Gaulle in France, with its appeals to tradition, the sense of community and national honour.

**United States.**—Although no major U.S. political party ever has assumed the name "Conservative," from the first years of the republic conservative ideas have been at work in American politics. Both the Federalist party of New England and the Republican party of Virginia exhibited different aspects of conservative thought and practice—the first with its emphasis on order and security, the latter with its attachment to the rural interest. During the Civil War, spokesmen for both North and South declared that theirs was the truly conservative stand.

The term "liberal" was seldom employed in the United States until the coming of World War I and did not become truly popular until the first administration of Pres. Franklin D. Roosevelt. During the Roosevelt years and World War II, however, conservatism became what Prof. Raymond English calls "the forbidden faith," the word carrying connotations of stupidity and selfishness. But about 1948 the spirits of conservatives began to revive; several books by reflective conservatives gained wide attention; and political leaders began once more to use the word approvingly. Among them was Sen. Robert A. Taft, who described himself as a "liberal conservative."

The failure of a really radical party to win the votes of any considerable number of Americans probably accounts for the lack of formal organization of American conservatives: the challenge was not strong enough to break down the barriers between the established Republican and Democratic parties. In the past, the absence of a distinct aristocracy and the numerous opportunities for personal advancement tended to discourage in the United States the formation of theoretical or class parties, whether conservative, liberal or radical. As the United States entered intimately into world affairs, however, and stood opposed to the threat of Soviet Communism, there became evident in America a growing desire for some political philosophy to oppose Marxism; and, as in Europe, the renewed popularity of conservative doctrines resulted. In practical politics, the popularity of Sen. Barry Goldwater of Arizona, the most vigorous figure among conservative politicians of the early 1960s, was an indication of this altered climate of opinion.

In the United States, as elsewhere, the particular forms assumed by the conservative impulse tend to be determined by the nation's traditional politics and social institutions. An American political conservative, at least in popular usage, is a person who believes strongly that the old pattern of American society ought not to be much altered. Typically, he holds by the federal constitution and maintains that it should be fairly strictly interpreted; he endeavours to oppose the tendency toward political centralization; he dislikes organizations on the grand scale, whether in govern-

ment, labour or business; he is a defender of private property and looks uneasily upon the increase of taxation and the "welfare" roles of the state; he is, of course, strongly opposed to Soviet power and international Communism; he emphasizes the individual personality as against collectivizing tendencies in 20th-century education and community life. In former years, this typical conservative was a Protestant; but from the early 1940s, for several reasons, American Roman Catholics tended toward conservatism in their politics and sometimes took the lead in conservative movements.

Along with a revival of conservative ideas during the late 1950s and early 1960s there was an emergence or reactivation of various groups of the "radical right," sharing some opinions with conservatives but looked upon with suspicion or distaste by many conservatives because of the virulence of their language or the impracticality of their views. The influence of such organizations was probably exaggerated both by their own members and by their liberal or radical opponents. In actuality, these groups appeared to be less powerful than they had been before World War II.

The most widely discussed of such associations was the John Birch Society, founded by Robert H. W. Welch, Jr., a Boston businessman, in 1958 and named for a U.S. intelligence officer killed by Chinese Communists soon after the end of World War II. Unlike most other "radical right" groups, the John Birch Society tended to attract a good many people of substance and education, including doctors, dentists and lawyers. Though its chapters existed in nearly every state, the society nevertheless remained comparatively small in membership, and enjoyed practical political success almost nowhere but in southern California. The movement's basic manual was *The Blue Book of the John Birch Society*; it was supplemented by a monthly bulletin called *American Opinion*. These publications asserted that Communism is a gigantic conspiracy to enslave mankind and that its main threat to the United States is not from Soviet military power but from internal subversion. Welch and some of his associates went so far as to declare that Dwight D. Eisenhower, Charles de Gaulle, and other eminent western statesmen were agents of Communist subversion. These extreme views were repeatedly ridiculed by leading American conservatives, as well as by liberals.

By the 1960s conservative societies had been formed by undergraduates on some 200 college campuses in the United States—an interesting reversal of the campus radicalism of the 1930s. The menace of the totalitarian society, it appeared, had begun to produce serious political discussion among members of the rising generation. Conservative opinions were also in the ascendancy in both major political parties. Out of this new pattern of politics, in both the United States and Europe, conceivably new general terms might arise to supplant, after a century and a half of use, both "conservative" and "liberal."

S. Meyer (ed.), *What Is Conservatism?* (1964).

**CONSERVATIVE PARTY (BRITISH).** In Great Britain, beginning about 1830, the name Conservative, traditionally ascribed to John Wilson Croker in an article published Jan. 1 1830, was applied to the direct descendants of the old Tory party (see WHIG AND TORY). In common use "Conservative" never entirely superseded "Tory." Its characteristic principles were the maintenance of existing institutions, political and ecclesiastical, the correction of proved abuses and resistance to violent change. With the secession of the Liberal Unionists from the Liberal party in 1886, the term "Unionist" also came into use, first applying to both the Conservative and Liberal Unionist parties and later, as the distinction between these disappeared,

as a further name, particularly in Scotland and Northern Ireland, for the party as a whole.

**Party Organization.**—Party organization developed directly from the constitutional or conservative associations established throughout the country after the Reform act of 1832. The National Union of Conservative and Constitutional Associations formed a confederation in 1867. From this grew the National Union of Conservative and Unionist Associations, with its constituency organizations grouped in 12 areas in England and Wales, and separate bodies for Scotland and Northern Ireland. After the general election of 1868, which followed the second Electoral Reform act of 1867, Benjamin Disraeli (afterward earl of Beaconsfield) devoted himself while out of office to the task of strengthening the party machine. One of his innovations was the setting up in 1870 of a Conservative central office. The National Union and the central office were for a short time distinct and separate bodies. In 1872, however, an arrangement was made by which the work of the National Union—which continued nevertheless to maintain its own individuality—became more closely associated with that of the party generally and its headquarters were moved under the same roof as the central office, where they have remained ever since.

In 1911 it was decided to create the post of chairman of the party organization, to take over the duties at the central office performed until then by the chief whip.

Members of both houses of parliament taking the party whip, adopted candidates and the executive committee of the National Union are responsible for electing and if necessary removing the leader of the party. The leader, who is the prime minister when the party is in office, is personally responsible for policy. He controls the parliamentary party through the whips. He appoints the chairman of the party organization, and through him has his contacts with the party in the country and the central office. He appoints the chairman of the Conservative research department, and through him controls the party's policy-forming committees.

The Conservative party by mid-20th century had acquired a remarkable record of internal loyalty. The effect of independent developments, such as the "Fourth party" in the parliament of 1880 and "Tory reform" during World War II, was stimulating rather than disruptive. The Primrose league and other similar outside organizations acted as co-operating agencies.

## PARLIAMENTARY HISTORY

**From the Reform Act to World War I.**—Between 1832 and 1915 political power alternated between Conservatives and Liberals. Liberal ministries predominated up to 1880 and Conservative ministries thereafter. In the earlier period Sir Robert Peel and Disraeli were the outstanding Conservative leaders. It fell to Peel to adapt Toryism to the changed conditions resulting from the Reform act of 1832 which had put the middle class in power. His policy, combining recognition of reform with proposals for economic and social improvement, was set out in the Tamworth manifesto of 1834. The election of 1841 gave the Conservatives a comfortable majority and Peel the opportunity to carry out his plans, but the prospect of a long period of Tory rule disappeared in 1846 when the repeal of the corn laws (*q.v.*) split the Conservative party. They did not have another clear majority until 1874. Disraeli, who had entered parliament in 1837 and had led the opposition to Peel on the corn law question, reorganized the party after this defeat. Convinced that further constitutional reform must come and that the future of the party lay in "Tory democracy," he used his influence to secure the passage of the Reform act of 1867. In his second administration (1874–80) he carried out an impressive program of social legislation.

The Conservatives lost the election of 1880 but in 1886, when the Liberal party split over Home Rule for Ireland, they formed a permanent alliance with the Liberal Unionists, led by Joseph Chamberlain. Thus reinforced, they held office for all but 3 of the next 20 years, led first by Lord Salisbury and then from 1902 to 1905 by Arthur Balfour. Electoral defeat, when it eventually came in 1906, was severe, being aggravated by a temporary

but serious division within the party on Joseph Chamberlain's policy of tariff reform. The new parliament contained only 157 Conservative and Liberal Unionist members. The party then went into opposition until May 1915 when, led by Andrew Bonar Law, who had succeeded Balfour in 1911, they joined H. H. Asquith's wartime coalition government.

**Between World Wars I and II.**—In Oct. 1922, at a meeting of Conservative members of parliament at the Carlton club, it was decided to fight the coming election as a separate party. The wartime coalition, led since 1916 by David Lloyd George and maintained at the "coupon" election of 1918, was dissolved. The election of Nov. 1922 gave the Conservatives 344 seats and a comfortable majority. Bonar Law became prime minister. From this time, apart from the two short-lived minority Labour governments of 1923–24 and 1929–31, the Conservative party was in office either alone or as the largest party in coalition governments until the election of July 1945.

The Labour party meanwhile replaced the Liberals as the main alternative administration. Up to the outbreak of World War II, Stanley Baldwin and Neville Chamberlain were the leading Conservative figures. Baldwin, who succeeded Bonar Law on the latter's resignation because of ill-health, was prime minister in 1923, 1924–29 and 1935–37. By virtue of his parliamentary majority he also held effective power in J. Ramsay MacDonald's National government of 1931–35. At the peak of his career Baldwin achieved an extraordinary ascendancy over both country and party, and is remembered particularly for his personal contribution to industrial conciliation after the general strike of 1926 and for his handling of the abdication crisis of 1936. Chamberlain, who succeeded him in 1937, had an impressive record as an administrator and social legislator, having been an outstandingly successful minister of health. He was the first chairman of the Conservative research department, which he founded in 1929. Like his father, Joseph Chamberlain, he believed in protection and fought persistently and eventually successfully for its reintroduction after the Conservative defeat on this issue in the election of 1923. On his conduct of foreign affairs, strong and differing opinions were held and the verdict of history is still uncertain. What is certain is that the bulk of the country supported the Munich agreement at the time.

**The Wartime Coalition.**—In May 1940, at the crisis of World War II, Winston Churchill succeeded Chamberlain as prime minister and formed a coalition in which the Conservatives, who at this time held 372 seats, were by far the strongest party. This was a memorable administration. During its five years of office, the war in Europe was won and the war in the far east set on the road to victory. Legislation, such as the Education act, 1944 (known as the Butler act), and the Family Allowances act, 1945, and a whole series of studies, of which the Beveridge report and the Employment Policy White Paper were the best known, planned for the social and economic development of postwar Britain. When, in the summer of 1945, the coalition was dissolved and the time for an election came, it was widely felt that this record, coupled with the immense personal prestige of Churchill, who had become leader of the party on Chamberlain's death in Nov. 1940, would ensure a Conservative victory. But the Conservatives had been in uninterrupted power for 14 years and the tide had now turned against them. Their defeat in the general election of 1945 was comparable in magnitude with those of 1846 and 1906. The parliament which met in Aug. 1945 contained only 189 Conservative members.

**In Opposition, 1945–51.**—In parliament, Conservative opposition was concentrated on the Labour government's nationalization and planning measures. In the country at large, the party reorganized itself and rethought its approach. Lord Woolton, as chairman of the party organization, put new life into the constituency organizations and new talent into the central office. Membership was increased, finances strengthened and a new appeal made to the young through the foundation and rapid expansion of the Young Conservative movement and the encouragement of younger parliamentary candidates by the removal of the financial barriers to candidature. Meanwhile, under R. A. Butler as

chairman of the Conservative research department and of the party's advisory committee on policy and political education, the party's attitude to the changed and rapidly changing conditions of the postwar world was set clearly before the nation in a series of policy statements of which the first and best known were the Industrial charter (1947) and the Agricultural charter (1948). The setting up of the Conservative political centre in 1946, working in close harmony with the research department, and the foundation of Swinton Conservative college a few years later gave the party better facilities than ever before for long-term political education. Under the stimulus of these reforms, the party rapidly regained confidence and strength, and having reduced the Labour government's majority from 140 to 6 in the general election of Feb. 1950, returned to power in the general election of Oct. 1951 with a majority of 17.

**In Office 1951-55.**—Winston Churchill's peacetime administration was pledged to "set the people free" and, having dealt with the immediate balance of payments crisis with which it was faced on taking office, was mainly notable at home for the liberalization of trade, the abolition of food rationing, the progressive removal of physical controls, an appreciable reduction in taxation, a major house-building program, and the return to private enterprise of the steel industry and road haulage. In commonwealth and colonial affairs, the period was principally one of preparation for advance: the return of law and order in Malaya and Kenya, the creation of the Federation of Rhodesia and Nyasaland, and the first steps toward the West Indies Federation. In foreign affairs, diplomatic initiatives by the foreign secretary, Anthony Eden, helped to break the deadlock in Korea and Indochina, to solve the Trieste dispute and to achieve agreement on the Austrian treaty. Despite strong Soviet pressure, Federal Germany's membership of the Western alliance was ratified in the London-Paris agreements (1954), and from this strong position negotiations were set in train for the summit conference of 1955. When, therefore, in the spring of 1955, Sir Winston Churchill resigned and Sir Anthony Eden, his successor as prime minister and leader of the party, went to the country, the Conservatives after less than four years in office could present themselves to the electorate as a united party with an impressive record of achievement both at home and abroad. The Labour opposition, however, was deeply divided on defense and other major issues. After a quiet election campaign, the Conservatives were returned for a second term of office with a majority increased to 59. The new parliament contained 345 Conservative and National Liberal members.

**Second Term 1955-59.**—Conservative party fortunes varied spectacularly between 1955 and 1959. At home, the government was soon in difficulties with a recurrence of inflation. The summit conference at Geneva in 1955 proved a disappointment. In the middle east the Suez crisis of 1956 confronted the government with the most dangerous and difficult situation since World War II, and its decision to intervene had world-wide repercussions. When, on Sir Anthony Eden's resignation in Jan. 1957, Harold Macmillan became prime minister and leader of the party, Conservative fortunes were at a low ebb and there was no early recovery. For the strict monetary measures enforced to defeat inflation, culminating in the 7% bank rate of Sept. 1957, and the Rent act, 1957, only added to the government's unpopularity. In 1957 and early 1958 a series of by-elections at North Lewisham, Rochdale, Kelvingrove and Torrington went against the Conservatives, the first three seats being won by Labour and the last by a Liberal.

Recovery, when it came, was rapid. Its causes were various: a general impression of wise leadership and strong government radiating gradually from Westminster and Whitehall to the country at large; economic recovery from both inflation and trade recession, bringing a welcome combination of stable prices and rising production and living standards; appreciation of the prime minister's efforts in early 1959 to lessen world tension and bring about another meeting of heads of government at the summit; the widely held impression that the Labour party was divided on vital issues and irrevocably wedded to out-of-date policies of nationalization and control. At the general election of Oct. 1959 the Conservative program, *The Next Five Years*, stressed the funda-

mentals of a strong pound, expanding trade and national unity if Great Britain were to fulfill its responsibilities at home and abroad. At the end of a hard-fought campaign the Conservatives were re-elected, with their overall majority increased to 100. Never since the Reform act of 1832 had a political party won three successive general elections, twice increasing its majority, while continuously in office. In the general election of Oct. 1964, however, the Conservatives, led by Sir Alec Douglas-Home, who had succeeded Macmillan as prime minister in Oct. 1963, won only 304 seats against Labour's 317 and the Liberals' 9. Douglas-Home resigned the party leadership in July 1965 and Edward Heath became his successor, elected by Conservative M.P.'s according to a newly established procedure. In the general election of March 1966 the Conservatives won only 253 seats against Labour's 363, the Liberals' 12 and 1 (Ulster) Republican Labour.

**CONSERVATORY, MUSICAL**, a public institution for instruction in music. The word derives from the Italian word *conservatorio* (workhouse), which in the Renaissance period was used to describe a type of orphanage sometimes attached to a hospital or hostel. The foundlings (*conservati*) were given instruction in music, and the *conservatori* were thus the first secular institutions equipped for musical tuition. Sixteenth-century schools of this kind were De' Poveri di Gesù Cristo and Della Pietà dei Turchini at Naples where Nicola Porpora and Leonardo Leo were pupils respectively, and Sant' Onofrio at Venice where Don Angelo Durante was a teacher.

The first secular school of music for the public at large was established in Paris by the Convention Nationale on Aug. 3, 1795 as a result of the efforts of the bandmaster, Bernard Sarrette. This was originally to have been called the Institut National de Musique, but the name Conservatoire de Musique, borrowed from the Italian, was decided upon to avoid confusion with the Institut des Sciences et Arts. The purpose of the Paris Conservatoire was, however, radically different from that of the Italian schools. Formed during the Terror, its aim was to train musicians to take part in public concerts, fêtes and celebrations organized by the republic. A state subsidy was granted, admission was by competitive examination and tuition was free. Later the curriculum was enlarged to include all branches of composition as well as all forms of instrumental and vocal technique. Classes were held in acting, thus enabling students to train for the Opéra, the Opéra Comique and the Comédie Française. Similar institutions were founded in the French provinces, and important prizes, scholarships and publications were sponsored, including the great *Encyclopédie de la Musique et Dictionnaire du Conservatoire* founded by Albert Lavignac and edited after his death in 1916 by Lionel de La Laurencie. Though many famous pupils of the conservatoire revolted against its academic severities it became the acknowledged centre of musical practice and erudition.

Throughout the 19th century the French model was copied, with modifications, in most European countries and in the United States. Conservatoires were founded in Milan (1807) and Naples (1808) and later in other Italian towns. Prague followed in 1811, Vienna in 1817 and in 1843 Mendelssohn and Schumann founded the Leipzig Konservatorium. Not all the German schools, however, followed the principles of the Conservatoire, and this was also true of similar institutes for musical education in Great Britain, of which the most notable were the Royal Academy of Music and the Royal College of Music (see MUSICAL SOCIETIES AND INSTITUTIONS). In the United States, among many schools of music owing their name to the French institution, the Boston Conservatory of Music (1867), the Peabody Conservatory of Music in Bal-

timore (1868) and the National Conservatory of Music, founded in New York in 1885, are the most important. Conservatories were also founded in Australia (the Adelaide Conservatorium, 1898) and Canada (the Toronto Conservatory of Music, 1886).

See C. Pierre, *Bernard Sarrette et les origines du Conservatoire National de Musique et de Déclamation* (1895). (E. L.R.)

**CONSETT**, an urban district. (1937) in the Consett parliamentary division of Durham, Eng., 12 mi. S.W. of Newcastle upon Tyne. Pop. (1961) 38,944. It stands on high ground by the right bank of the Derwent. At Shotley Bridge, a German colony of metalworkers, making swords and knives, was established in the 17th century. Coal mining, metalworking, iron smelting, coking and the making of furnace linings are the main industries. A Roman road crossed the Derwent at nearby Ebchester.

**CONSIDÉRANT, VICTOR PROSPER** (1808–1893), French socialist, was born at Salins (Jura) on Oct. 12, 1808. Educated at the École Polytechnique in Paris, he entered the French army as an engineer, rising to the rank of captain. He resigned his commission in 1831 in order to devote himself to advancing the doctrines of F. M. C. Fourier. On the death of Fourier in 1837 he became the acknowledged head of the movement, and took charge of *La Phalange*, the organ of Fourierism. He also established *phalanges* at Condé-sur-Vesgres and elsewhere. During this period he published his *Destinée sociale* (1834–38), undoubtedly the most able and important work of the Fourierist school. After the revolution of 1848 he was elected to the constituent assembly for the *département* of the Seine. Considérant's share in the "demonstration" under the leadership of Alexandre Ledru-Rollin on June 13, 1849, made it necessary for him to leave France. He made Brussels his headquarters and from there made his visits to the United States. On the second of these visits he founded near Dallas, Tex., the short-lived communistic colony of La Réunion. He returned to Paris in 1869 and died there on Dec. 27, 1893. The most important of Considérant's other writings were *Exposition du système de Fourier* (1845), *Principes du socialisme* (1847), *Théorie du droit de propriété et du droit au travail* (1848). See also FOURIER, (FRANÇOIS MARIE) CHARLES.

**CONSISTORY**, a gathering of ecclesiastical persons for the purpose of administering justice or transacting business. The term (Lat. *consistorium*, literally, a "standing place," hence meeting place) first was applied to the audience chamber in which the emperor received petitions and gave judgment; it soon came to mean also the persons who took part in the deliberation, and, by an extension of meaning, a tribunal or jurisdiction. But it has long been employed exclusively to denote ecclesiastical meetings, most particularly meetings of the college of cardinals with the pope as president.

The "consistory" was a form of consultation adopted by the popes when, about the 13th century, particular Roman councils ceased to be held. In earlier times dogmatic and disciplinary questions were discussed in such councils or, if the matter was less important or the bishops could not be convened, in an assembly of the Roman clergy, called the *presbyterium*. As the institution of the cardinalate (see CARDINAL) became more significant and authoritative, especially under Nicholas II (1058–61), the college of cardinals, assembled in regular meetings called consistories, became the stable counselors of the popes. In the course of time more complicated business came to be assigned to various commissions of cardinals and, with the formal organization of the Roman congregations by Sixtus V (1585–90), the active function of the consistories diminished. In modern times the consistories, which continue to be held at irregular intervals, are largely ceremonial. The limited matters they deal with have already been arranged by the pope himself or by the Sacred Congregation of the Consistory, and the request for the opinion of the cardinals ("Quid vobis videtur?") is a formality; in reality such consistories are a form of solemn promulgation of certain special papal acts.

There are three kinds of consistory: the secret consistory, in which only the cardinals take part; the public consistory, to which are admitted persons from outside and a fairly large audience; and finally, the semipublic consistory, in which the bishops present in Rome take part with the cardinals and are invited to state their

opinions. The secret consistory, which corresponds most closely to the original concept, deals with such matters of general interest as the creation of cardinals, appointments to dioceses and other higher benefices (hence called "consistorial"), the creation, union or division of dioceses, the conferring of the pallium, etc. These are held in the Hall of the Consistory, where, after all non-cardinals have left the room, the cardinals range themselves in a circle about the pontiff in a complicated pattern of precedence, so that the senior cardinal bishop is at his right and the senior cardinal deacon at his left. It is called a secret consistory only in the sense that participation is limited to the cardinals. Actually the proceedings are published in the official journal of the Holy See, *Acta Apostolicae Sedis*. The pope customarily opens the meeting with a discourse, or "consistorial allocution," devoted to current issues or events of greater moment directly or indirectly affecting the church as a whole.

The public consistory now is held only for the ceremony of conferring the hat on newly created cardinals; formerly the popes used to receive in public consistory sovereigns and certain other great persons, but in this case the consistory was not deliberative in form. The only semipublic consistory is that immediately preceding a canonization (see CANONIZATION).

In the Church of England the term consistory court denotes the bishop's court for administration of church law in his diocese. Consistory court or kirk session is the lowest court in some Presbyterian churches, consisting of the minister and elders of the congregation. See also ECCLESIASTICAL LAW (ENGLISH).

(J. J. RE.)

**CONSISTORY COURTS**; see ECCLESIASTICAL LAW (ENGLISH).

**CONSOLS**, an abbreviation of Consolidated Annuities, a form of British government stock that originated in 1751. The first issue of Consols carried a 3% interest rate until the conversion operation of 1888 reduced the rate to 2½% for the next 14 years and thereafter to 2½%. Between Dec. 1926 and March 1932, 4% Consolidated Loan stock was issued, also known as Consols. Before World War I, Consols formed the larger part of Britain's "funded debt"; i.e., that portion of the national debt the redemption of which is at the option of the government. By March 31, 1961, however, the national debt had, as a result of loans raised through two world wars, reached £28,254,000,000, and at that date 2½% Consols, of which £275,720,800 were outstanding, represented only 1% of the total. At the same date £378,554,381 of 4% Consols were outstanding. After Feb. 1, 1957, the latter were redeemable by the government on three months' notice; the 2½% stock, since April 5, 1923, has been in theory redeemable at any time at the government's option, but in practice it is virtually an irredeemable stock whose price tends to vary inversely to the bank rate.

(B. P. W.)

**CONSORT**, in general, a partner or associate, but more particularly a husband or wife. The word is also used in conjunction with some titles, as "queen consort," "prince consort." Under British law, the queen consort is a subject, but has certain privileges. By the Treason act, 1351, plotting and imagining her death is high treason, as is also the commission of adultery with her. With regard to the acquisition and disposal of property, the incurring of rights and liabilities under contract, suing and being sued, a queen consort is regarded as a feme sole or a single woman (Queen Consort act, 1540; Crown Private Estate act, 1800). In other words she may sue and be sued as a private subject but has her own ceremonial officers and appears in the courts through her own attorney general and solicitor general. When the husband of a queen consort dies, she becomes a queen dowager.

A queen regnant, holding the crown in her own right, has all the prerogatives of a sovereign. At common law the husband of a queen regnant is an ordinary subject with no special privileges or precedence in the absence of specific conferment. Hence the position of the husbands of queens regnant in British history has varied. When Queen Mary I married Philip of Spain, every conceivable precaution was taken to ensure that the queen alone should exercise the powers of the crown, although official docu-

ments were to be issued under joint names. The husband of Queen Mary II occupied the throne jointly with her as William III, but the husband of Queen Anne, George of Denmark, occupied no definite position apart from the special nature of his naturalization in 1689. The position of Prince Albert of Saxe-Coburg-Gotha, the husband of Queen Victoria, was somewhat similar, he being naturalized shortly before the marriage, but he was granted precedence next to the queen immediately after the marriage, and in 1857 was given the formal title of prince consort. This title was not conferred upon the duke of Edinburgh after the accession of his wife as Queen Elizabeth II, but in 1952 he was invested with precedence next to the queen. (M. C. ME.)

**CONSPIRACY**, in Anglo-American law, is usually described as an agreement between two or more persons to commit an unlawful act or to accomplish a lawful end by unlawful means. This definition is delusively simple, however, for each of its terms has been the object of extended judicial exposition. Criminal conspiracy is perhaps the most amorphous area in the Anglo-American law of crimes. It has never been subjected to precise definition either by courts or legislatures. In most jurisdictions, for example, the "unlawful" end of the conspiracy need not be one which would be criminal if accomplished by a single individual; but courts have not always agreed as to what constitutes an "unlawful" objective for these purposes. Ordinarily conspiracy is the object of criminal prosecution. In some situations, however, it may provide the basis for a tort suit by the injured party.

In the old English law, the crime of conspiracy consisted of abuse of the processes of criminal justice and is related historically to the tort of malicious prosecution. Thus the third Ordinance of Conspirators (33 Edw. I, 1305) condemned conspiracy to bring a false and malicious presentment or to procure a false appeal. The modern conception of conspiracy as an agreement to produce any unlawful or oppressive end did not emerge until the 17th century and is the product of law and procedures developed in the star chamber. Not until after the Restoration did the common-law courts recognize the offense in its modern form. In the 18th century, agreements of workmen for concerted action to raise their wages were defined as criminal conspiracies. Prosecutions for conspiracy in labour disputes continued in England until the Conspiracy and Protection of Property act of 1875 excluded ordinary trade-union activity from the definition of the offense. (See LABOUR LAW; STRIKES AND LOCKOUTS; LABOUR [TRADE] UNION.)

**United States.**—The law of criminal conspiracy in the United States derives directly from the law that emerged in England during the 17th century. As in England, the early history of conspiracy law is closely associated with labour disputes. In 1806 a Pennsylvania court declared criminal a combination of journeymen cordwainers to raise wages. This precedent was followed in other U.S. jurisdictions. In 1842 the Massachusetts court, through Chief Justice Shaw, reached a contrary result in the celebrated case of *Commonwealth v. Hunt*, 4 Met. 111. The right of employees to engage in "concerted activities for the purpose of collective bargaining or other mutual aid or protection" was affirmed by congress in the National Labour Relations act of 1935.

Administration of the law of criminal conspiracy in the United States has given rise to a number of recurring issues. In many of the states the objective of the conspiracy need not be a criminal act. Thus, in the case of *Commonwealth v. Donoghue*, 250 Kv. 343 (1933), a sharply divided court held criminal a combination of persons who had loaned money at usurious rates of interest, even though no crime of usury was recognized in the state. The question of what kind of criminal intent must be established has raised questions, the issue being whether it must be shown that defendants were aware that the object of the combination was unlawful. The chief problems, however, are associated with the definition of the conspiratorial agreement. It is clear that the agreement need not be accompanied by any particular formalities and even that individual conspirators need not know the identity or of the existence of all the other conspirators.

Conspiracies often take one of two primary forms or a com-

bination of both. The "chain conspiracy" involves a series of transactions all directed to a common unlawful objective. Thus in *U.S. v. Bruno*, 105 F. 2d 921 (1939), illegal narcotics were brought into the country by smugglers who sold the drugs to middlemen who, in turn, sold to retailers. All these persons were held to be part of the same conspiracy to violate the federal narcotics laws, even though the smugglers did not know the identity of the retailers. The second characteristic form is the "wheel conspiracy," in which illegal contacts with a single individual at the "hub" of the combination are deemed a sufficient nexus to unite in the same conspiracy all persons making such contacts. Thus in the English case of *Rex v. Meyrick and Ribuffi*, 21 Cr. App. R. 94 (1929), three night-club operators who bribed the same police officer were held to have conspired with each other to effect public mischief, even though each was ignorant of the identity of the other. With concepts so elastic, definition of the conspiratorial relationship is the source of difficulty and even unfairness.

The law of criminal conspiracy in the federal system is entirely statutory. Many of the regulatory statutes, such as the Sherman Anti-Trust act, have special conspiracy provisions designed to enforce the policy of the particular statutes of which they are a part (see *MONOPOLY: Legal Aspects*). In addition, the federal criminal code contains a general conspiracy section applicable to situations not covered by the special provisions. Under the general statute the object of the conspiracy must be to defraud or commit an offense against the United States. The scope of the offense is narrowed further by the requirement that at least one of the conspirators must commit some overt act to effect the object of the conspiracy before the combination is punishable. Finally, under the general statute criminal conspiracies are felonies except when the object of the conspiracy is a misdemeanor. In the latter case the conspiracy is punishable only as a misdemeanor. Conspiracy prosecutions are more frequently brought in the federal practice than in most state systems of criminal justice. (F. A. A.)

**England.**—At common law, conspiracy is an indictable misdemeanor, but by s. 4 of the Offences Against the Person act (1861) conspiracy to murder, whether the victim be a subject of the king or not, and whether he is within the king's dominions or not, was declared also a misdemeanor and is punishable by penal servitude not exceeding ten years. Conspiracy to commit treason is treason. It is also interesting to note that the legislature interfered in the case of illegal agreements with respect to bidding at auctions and made it an offense for a dealer to abstain from bidding for a consideration (Auctions Bidding Agreements act, 1927).

Criminal conspiracy may be classified as follows: (1) to cheat and defraud; (2) to injure by wrongful acts other than fraudulent acts; (3) to commit any offense punishable by law; (4) to do any act with intent to pervert the course of justice; (5) conspiracies or combinations in relation to trade and employments. A husband and a wife cannot commit the offense as they are legally one person, but they can conspire with a third person.

The most important question in the law of conspiracy, apart from the statute law affecting labourers, is how far things which may be lawfully done by individuals can become unlawful when done by individuals acting in concert.

The same question arises in the law of tort. Since *Crofter Hend Woven Harris Tweed Co. v. Veitch* (1942 Appeal Cases 435), there can be no doubt that a conspiracy in given circumstances can itself constitute an actionable wrong if damage ensues. In his judgment in this case Lord Simon drew the distinction between the crime and the civil wrong: "The crime consists in the agreement though in most cases overt acts done in pursuance of the combination are available to prove the fact of agreement. But the tort of conspiracy is constituted only if the agreed combination is carried into effect in a greater or less degree and damage to the plaintiff is thereby produced." Lord Simon also defined the boundary line between the lawful and the unlawful agreement: "I am content to say that, unless the real and predominant purpose is to advance the defendants' lawful interests in a matter where the defendants honestly believe that those interests would directly suffer if the action taken against the plaintiffs was not taken."

a combination fully to damage a man in his trade is unlawful. Although most of the cases have dealt with trade rivalry in some form or other, I do not see why the proposition as to the conditions under which conspiracy becomes a tort should be limited to trade competition."

An important exception to the general law relating to conspiracy and interference with trade is created by s. 3 of the Trade Disputes act, 1906, which provides that an act done by a person in contemplation or furtherance of a trade dispute shall not be actionable on the ground only that it induces some other person to break a contract of employment or that it is an interference with the trade, business or employment of some other person, or with the right of some other person to dispose of his capital or labour as he wills. The words "in contemplation or furtherance," "trade dispute" and "interference with the trade, business, or employment of some other persons" necessitated a good deal of judicial interpretation. The judgments in *D. C. Thomson v. Deakin* (1953 Chancery 646) contain useful summaries of the relevant authorities, but important issues of interpretation are involved in the case of *Rookes v. Barnard and others* (1962) and are likely to be decided eventually by the house of lords. (W. T. Ws.)

**Other Countries.**—No conception of conspiracy as broad as that recognized in the Anglo-American legal system is to be found in any of the continental codes. In some of the European countries, such as France, punishment of crimes may be enhanced when the offense was committed by more than one person acting in concert. In most civil-law countries the punishment of agreements to commit offenses irrespective of whether the criminal purpose was attempted or executed is largely confined to political offenses against the state. Some extension of the conspiracy idea in other areas has occurred, however. Thus in the Italian code of 1930 association for the purpose of committing more than one crime was made criminal. The Yugoslav code of 1951 makes criminal the organization of a group for the purpose of committing any offense punishable by more than five years' imprisonment. As early as 1932 Germany punished agreements to commit "major crimes against life." None of these provisions, however, has the generality of the Anglo-American concept. None, for example, condemns agreements to commit acts not otherwise criminal.

(F. A. A.)

**CONSTABLE, ARCHIBALD** (1774–1827), Scottish publisher of the *Encyclopædia Britannica* and works of Sir Walter Scott, was born in Carnbee, Fifeshire, on Feb. 24, 1774. After local schooling and an apprenticeship to a bookseller, he lived briefly in London, then opened a rare-book shop in Edinburgh in 1795. In that year he also became a publisher with a commercially successful account of bloody riots in Granada. Shrewd and hard-driving, he soon came to be called in Edinburgh's literary circles the "Napoleon of Publishing" and "The Crafty." In 1802 he founded the *Edinburgh Review and Critical Journal*, a smart, savage and witty magazine whose notable contributors were headed by Sir Francis Jeffrey and Sydney Smith. Constable flouted tradition by paying contributors as much as £1,000 for a philosophical dissertation or £20 for a single-page book review. His regular list of authors included Sir Walter Scott, of whose works he published *The Lay of the Last Minstrel*, the *Waverley* novels and *Marmion*, for which he paid Scott 1,000 guineas.

From 1810 to 1814 Constable gradually acquired ownership of the *Encyclopædia Britannica* from the heirs of Andrew Bell. His prime accomplishment as its publisher was the issuance of a six-volume supplement to the 4th, 5th and 6th editions from 1816 to 1824, generally heralded for its scholarship and authority (see *ENCYCLOPÆDIA*). Through overspeculation and failure of his London agents in 1826, Constable went bankrupt, the debacle also involving Scott. In debt for about £250,000, Constable started anew, issuing in 1827 *Constable's Miscellany of Original and Selected Works in Literature, Art and Science*, one of the first efforts to popularize wholesome literature in inexpensive editions. That same year, on July 21, he died in Edinburgh. His son, Thomas (1812–1881), later maintained the company with his own son, Archibald, who retired in 1893. The firm continued as T. and A. Constable.

See Thomas Constable, *Archibald Constable and His Literary Correspondents*, 3 vol. (1873); Herman Kogan, *The Great EB* (1958). (Hn. K.)

**CONSTABLE, HENRY** (1562–1613), English poet whose sonnet sequence *Diana* shows French influence, but whose spiritual sonnets are of a much higher quality, was born in 1562. He visited Scotland and Europe in 1583–85 in the service of Sir Francis Walsingham. He became a Roman Catholic in 1589 and remained abroad after serving in the earl of Essex' expedition to Rouen, France, in 1591. In 1598 he was sent by the pope to Scotland to indicate the terms on which James VI would be supported in his claim to the English throne. He went to England in 1603 but was arrested in May 1604 and was frequently in prison until he left England in 1610. He died at Liège, Belg., on Oct. 9, 1613.

In 1589 he published anonymously in Paris *Examen pacifique de la Doctrine des Huguenots*, translated into English and published in 1623 as *The Catholike Moderator*. His *Diana, the praises of his Mistress in certain sweet sonnets*, by H.C. (1592) contains 23 poems. The 1594 reprint contains 76 poems, many by other hands. He himself said that he wrote 63 secular poems.

The second edition of *Diana* was reprinted by E. Arber in *The English Garner*, vol. ii (1879). Sixteen *Spiritual Sonnettes* found in manuscript and attributed to Constable were edited by Thomas Park in *Heliconia*, vol. ii (1815). Constable's works were edited by W. C. Hazlitt (1859).

See L. I. Guiney, *Recusant Poets With a Selection From Their Work* (1938); G. Wickes, "Henry Constable, Poet and Courtier," *Biographical Studies 1534–1829*, vol. ii, no. 4 (1954). (M. H. D.)

**CONSTABLE, JOHN** (1776–1837), one of the greatest English landscape painters, was born at East Bergholt, Suffolk, on June 11, 1776, the second son of a wealthy miller, Golding Constable. Originally intended for the church, he began to take an interest in landscape painting while he was at Dedham grammar school, which he left about 1793 to work for his father. During his spare time he studied painting and met Sir George Beaumont, a dilettante painter and patron, whose collection included drawings by Thomas Girtin and Claude Lorrain's "Hagar and Ishmael," the sight of which fired Constable's enthusiasm. His keen artistic interest was such that his father allowed him to visit London in 1795, where the engraver John Thomas Smith taught him etching. Constable's biographer, C. R. Leslie, relates that he also sought advice from the landscape painter Joseph Farington (1747–1821) in 1795, but Farington's *Diary* gives Feb. 25, 1798, as the date of their first meeting.

Recalled to his father's countinghouse in March 1797, Constable was unable to follow his vocation until 1799, when in December he was listed as a probationer of the Royal Academy schools, and in Feb. 1800 became a full student. After two failures he exhibited

COPYRIGHT THE FRICK COLLECTION, NEW YORK

"SALISBURY CATHEDRAL FROM THE BISHOP'S GARDEN," BY JOHN CONSTABLE. IN THE FRICK COLLECTION

his first landscape at the academy in 1802. A year previously John Reade had commissioned him to paint the "Old Hall, East Bergholt" (formerly Misses K. and M. Gore collection), a topographical picture that was described by Farington (*Diary*, July 13, 1801) as influenced by Beaumont, but that in the fresh, liquid painting of the trees and sky already hints at a distinctive style: Constable was by now convinced that there was "room enough for a natural painter." Nevertheless, his development was slow, and he remained largely self-taught, studying "truth at secondhand" in the works of Jacob van Ruisdael, Claude, Richard Wilson and Thomas Gainsborough. Some marine drawings in the manner of W. van de Velde were executed at Deal in 1803, and in 1804 and 1808 he painted altarpieces for the churches at Branham and Nayland, which stylistically owe much to Benjamin West, for whose early encouragement Constable was always grateful. He it was who saved Constable from the drudgery of a drawing-mastership, offered by the kindly intentioned archdeacon John Fisher, another of the artist's lifelong friends and patrons. In 1806 Constable toured the Lake district, and the sketches of this date are strongly influenced by the work of J. R. Cozens and Girtin. Between 1807-08 he copied paintings in Lord Dysart's collection, including portraits by Sir Joshua Reynolds, an artist whom Constable always admired. Besides copying, he was compelled to supplement his slender income by portraiture until 1814. By this time, however, he had acquired an assistant, John Dunthorne (1798-1832), the son of an East Bergholt plumber and glazier with whom Constable as a schoolboy had first studied painting.

The year 1811 marked a turning point in his career. He then exhibited the large "Dedham Vale" (Maj. R. G. Proby collection) at the academy, an ambitious panoramic view of Essex countryside seen at midday in brilliant early summer sunlight. This contains the almost fully matured features characteristic of his art. He also fell in love with Maria Bicknell, whom he was not allowed to marry until 1816, after the death of his father had assured him a measure of financial security and nullified the Bicknell family's objections. By 1819 two legacies each of £4,000 alleviated domestic anxieties, and his genius was at least acknowledged by his election in November to the associateship of the academy.

During the years 1811-26 Constable unwaveringly pursued a lonely road of experiment and discovery, against the accepted teaching of his day, in the means of rendering the observed appearance of landscape. The evidence of this search lies in the series of over 300 drawings and oil studies which in 1888 were bequeathed to the Victoria and Albert museum, London, by the painter's daughter Miss Isabel Constable. These studies show the artist steadily acquiring a bolder, freer handling of paint, to record, within traditional schemes of composition, the fleeting aspects of landscape as perceived under varying conditions of light and weather. The disparity between Constable's oil sketches and his big finished pictures which occurs so frequently—the nervous, trembling brushstroke and emotional tension on the one hand, as opposed to the calm, reflective quality on the other—may best be explained as the artist's recreation of a mood, of a remembered vision, in the tranquillity of his studio. A comparison between the study for "The Hay Wain," c. 1821 (Victoria and Albert museum) and the finished composition in the National gallery, London, with its additions and alterations, shows the working out of this double creative process, which is also described in Wordsworth's poetry and is typical of the Romantic revival in art and literature as a whole. Notable works of this period are "Boat-building" (Royal Academy, 1815; Victoria and Albert museum), painted entirely in the open air, near Flatford mill; "Flatford Mill" (Royal Academy, 1817; Tate gallery, London); "The White Horse" (Royal Academy, 1819; Frick collection, New York), his first six-foot canvas; "The Hay Wain" (Royal Academy, 1821; National gallery); "Salisbury Cathedral From the Bishop's Grounds" (Royal Academy, 1823; Victoria and Albert museum), the first of several versions; and "The Leaping Horse" (Royal Academy, 1825; Diploma gallery, Royal Academy), for which a grand, unified, full-scale study exists in the Victoria and Albert museum. The "Salisbury Cathedral" of 1823 is painted in a new technique of blobs and pure colour, with scumblings and

heavy impasto, and contains those elements so prized by Constable: "my light—my dews—my breezes—my bloom and my freshness"—qualities as yet absent from landscape painting. During 1821-22, Constable painted a series of cloud studies remarkable for their close accuracy of observation and sustained quality. This intensive study of the atmosphere was inspired by the researches of Luke Howard, fellow of the Royal society, whose standard classification of cloud structure provided Constable with a scientific framework to serve his pictorial ends. Constable's admiration for the older masters of landscape—Rubens, Ruisdael, Titian and above all Claude—steadily increased, and in 1823 he spent six weeks copying landscapes in Beaumont's collection.

The French were the first to acclaim Constable publicly, when at the Paris Salon of 1824 he showed three paintings, including "The Hay Wain," and again at Lille in 1825, where he exhibited "The White Horse." On both occasions he was awarded a gold medal. "The Hay Wain" had been purchased by John Arrow-smith, an Anglo-French dealer who, with the print seller Schroth, imported many Constables into France. Not until 1829 did the Royal Academy grudgingly admit Constable as a full academician by which time it came as a hollow honour. Although early in 1828 he had inherited £20,000 from his father-in-law, this new-found security was soon blighted by the death of his wife later that year.

The work of the last ten years of Constable's career shows greater diversity of development, and he attempted to infuse more of the spontaneity of his sketches into the larger compositions, such as the windswept, impressionistic "Hadleigh Castle" of 1829 (large study in the Tate gallery). Alternating with these broadly treated atmospheric works are carefully detailed paintings as "The Valley Farm" (1835; Tate gallery), or "The Cornfield" (1826), purchased by private subscription and presented to the National gallery soon after Constable's death. The most ambitious achievement of this period was the "Waterloo Bridge From Whitehall Stairs" (Royal Academy, 1832; Lord Glenconner), projected about 1819 (in 1824 he exhibited a smaller "Waterloo"), a sparkling, light-filled composition in which the distant vista of the bridge is framed by a foreground of trees, boats and buildings in the manner of Claude. As in many works of this date, Constable made extensive use of a palette-knife technique, notably in "The Cenotaph" (Royal Academy, 1836; Tate gallery), with which he pays tribute to Reynolds, to whose memory the cenotaph had been erected at Coleorton (Beaumont's house), and reflects in its gentle melancholy his own sombre mood. In 1833 David Lucas had published a splendid series of mezzotints after Constable's paintings entitled *English Landscape*. Constable's sudden death on March 31, 1837, could be attributed to no discoverable disease.

Constable's importance lies in his having brought to the art of landscape painting a highly original creative vision of such power as to convey to the spectator his own direct passion. Apparently mundane, trivial objects were seen afresh and painted with the devoted concern of a naturalist's observation. Naturalism for Constable meant indeed an aversion to the ideal landscape and to borrowed ideas. He may truly be considered the father of modern landscape painting and a liberating force on mid-19th century French landscape tradition. See also PAINTING; LANDSCAPE PAINTING.

**CONSTABLE**, the title of a great officer of state in western European countries from medieval times, and of certain executive legal officials in Great Britain and the United States.

**Officers of State.**—The title of *comes stabuli* (see COUNT) is found in the Roman and particularly in the East Roman or Byzantine empire from the 5th century A.D. as that of the head of the stables at the imperial court. The Franks borrowed the title,

and under the Merovingian and Carolingian kings of western Europe the *comes stabuli* was in charge of the royal stud, with the marshal (*marescallus*) as his subordinate officer. Both these important palace officials sometimes deputized for the king in command of the army. In the 11th century the constable (*connétable*) of France became one of the five great officers of state, with certain limited powers of jurisdiction and with command of the cavalry. With the decline of the office of seneschal (*g.v.*) the constable's military duties and judicial powers increased till by mid-14th century he held supreme military command of the army: at the height of his power, he possessed the right to be addressed as "cousin" by the king and took precedence immediately after him. After the treason of constable duc de Bourbon (1523), however, the kings distrusted the office, and for many years in the 16th century it was allowed to remain vacant. Suppressed in 1627, after the death of François de Bonne, duc de Lesdiguières, it was revived by Napoleon I, who appointed his brother Louis Bonaparte constable. It was finally abolished on the restoration of the Bourbons.

The constable and marshal in France both held courts to implement their judicial powers. Having similar duties, they fused into one body (*connétable et maréchaussée*) during Louis XI's reign. Until the middle of the 14th century the constable and the marshal personally presided over their courts, but as military operations increased a lieutenant conducted duties in their name. Early in the 15th century he assumed the title of *lieutenant général*. In addition to civil and criminal jurisdiction, which included all military persons and causes, the court's jurisdiction extended to include persons with no legal domicile, previously convicted criminals, murder, robbery and other acts of violence. This often resulted in disputes with the ordinary courts. After the 15th century the court's power declined, and its duties were principally administrative, but it survived until the Revolution.

The kings of Castile, of Navarre, of Naples and of Portugal also had their constables. The hereditary title of constable (*constable*) of Castile belongs to the house of Velasco, that of grand constable of Navarre to the dukes of Berwick and Alba. The Colonna family became hereditary grand constables of Naples in 1450. In Portugal, Nuno Álvares Pereira (1360-1431) was appointed constable in 1385. His daughter's marriage to King John I's bastard son Afonso gave rise to the ducal line of Braganza, who were hereditary grand constables until the 8th duke succeeded to the throne in 1640.

In Scotland the office of constable, introduced in the 12th century, became hereditary in the Comyn family in the 13th century and in the Hay family (later earls of Erroll) from 1314. Their status was fixed by an act of parliament in 1681, when the lord high constable was given precedence before every other hereditary honour after the blood royal and rank in all royal armies next to the king. His judicial powers extend to all disorders committed within four miles of the sovereign's person or of the parliament or council representing him, and he has the charge and guarding of the king on ceremonial occasions.

In England the office of constable, which was similar to that of the pre-Conquest *staller*, was in existence in Henry I's reign. The constable and marshal were principally in command of the army, though they had duties at the king's court. The office was hereditary in the family of Milo of Gloucester (earls of Hereford from 1141), then in the Bohun family (earls of Hereford from 1199 to 1373). Edward Stafford, 3rd duke of Buckingham, claimed the office of lord high constable as heir of the Bohuns, but after his attainder (1521) it was revived only occasionally. Lord high constables are now appointed only for coronations. The constable and marshal's court, also known as the court of chivalry, came into existence at least as early as the reign of Edward I.

**Local Officers.**—Officers with important military commands and in control of garrisons and castles were also known as constables; e.g., the constables of Windsor, Dover, Caernarvon, Conway, Harlech and Flint castles and of the Tower of London, still existing in the 20th century. Sometimes the appointment was coupled with that of conservator (later justice) of the peace, who

assisted the sheriff in enforcing the law. This gave rise to constables exercising civil jurisdiction. Under the Statute of Winchester (1285) the civil and military organizations were linked. A chief or high constable was appointed in every hundred or franchise, who was responsible for suppressing riots and violent crimes and for arming the militia to enable him to do so. Under him were petty constables in each tithing or village. The high and petty or parish constables remained the executive legal officers in counties until the County Police acts of 1839 and 1840 allowed justices in quarter sessions to establish a paid police force. The office of high constable, which latterly had chiefly been concerned with inspecting weights and measures, suppressing cattle disease and levying and collecting the county rate, was abolished in 1869. In Scotland, bodies of high constables, formed to curb riots, etc., still exist at Edinburgh, Leith, Perth and Holyroodhouse, the last-named being prominent on state occasions.

By the Parish Constables act of 1842, constables were to be concerned only with the security of persons and property and no longer with the keeping of the peace. Vestries (later parish councils) were allowed to decide if one or more of these should be paid. By the Parish Constables act of 1872 appointments were no longer to be made unless required by a resolution of general or quarter sessions or requested by the resolution of a vestry. (See further POLICE.)

Special constables are peace officers appointed to act on emergencies when the ordinary police force is thought insufficient.

In the rural districts of the United States the constable had the same status as in England before the act of 1842, but during the 20th century gradually lost most of his power in criminal matters to the uniformed police, being thereafter chiefly concerned with the issuing of writs, processes and election notices. Virginia totally abolished the office, as also did many counties in other states. Candidates for election were often not forthcoming. The office of high constable existed in Philadelphia and New York—in the latter city until 1830. (P. W. M.-S.)

**CONSTANCE** (KONSTANZ), a town of Germany which after partition of the nation following World War II was in the *Land* (state) of Baden-Württemberg in the Federal Republic of Germany. It lies 1,312 ft. above sea level at the point where the Rhine flows out of Lake Constance. Pop. (1959 est.) 51,666. Of the fortifications of the medieval town, on the left bank of the Rhine, only the Schnetz gate, two towers and a part of the town wall remain. The modern residential and industrial areas, recreation grounds and barracks are all north of the river in the district of Petershausen and the adjacent suburbs.

By the harbour of the old town is the Kaufhaus (warehouse) built in 1388 and, across the wide market place, stands the Renaissance-style town hall (1585). Near the Upper market is the Gothic Rosgarten museum, once the guild house of the butchers, and between these and the Rhine stands the 11th-century minster which was the cathedral until 1821, the diocese of Constance having once been the greatest in Germany. Among medieval houses are the city library and picture gallery and a house with frescoes (c. 1300) showing the history of linen weaving. In Niederburg is the unchanged medieval Dominican monastery of Zoffingen. The modern state technical college stands on the banks of the Rhine.

Constance is about 40 mi. from the Black Forest and at the end of the Black Forest and upper Rhine railways and is connected to the Swiss railway network. The shipping routes of the lake converge on Constance harbour and the airfield is used by small aircraft. There are textile concerns, engineering works and electrical and chemical works. Because of its beautiful setting Constance is the most popular tourist resort on the lake.

A Roman fort, established there in the reign of Claudius (A.D. 41-54), was invaded in the 3rd century by the Alamanni who, in about 600, founded a bishop's see. The emperor Frederick I Barbarossa made peace there with the Lombard states in 1183. In the 13th century the export of linen brought great prosperity and in the 14th century the townspeople freed themselves from episcopal rule. Constance, then a cultural centre, became an imperial city and head of a powerful confederacy of towns. The

14th-century mystic Heinrich Suso entered a monastery there. During the council of Constance (*see* CONSTANCE, COUNCIL OF) John Huss was tried and burned. In 1417 at Constance Frederick I of Hohenzollern was enfeoffed with the electorate of Brandenburg (*q.v.*) by King Sigismund. During the Reformation Constance became Protestant under the influence of Zwingli and the bishop transferred his see to Meersburg on the north coast of the lake. After the defeat of the Protestants in 1547 Constance lost its rights as an imperial city, became Catholic again and fell under Austrian rule, until it became part of the then newly formed grand duchy of Baden in 1805. In 1633 the Swedes laid siege to the city. During the 19th century many collections and archives were removed, churches and monasteries suppressed and most of the city fortifications pulled down. Nevertheless, Constance remains the cultural and economic centre of the district. (O. F.)

**CONSTANCE, COUNCIL OF**, a church council convoked, under pressure from the emperor Sigismund, by John XXIII (1410–15), one of the three popes who divided the allegiance of Christendom at the time and generally considered to have been an antipope (an opinion shared by the pope who ascended the throne in 1958, also as John XXIII). The two other papal claimants were Gregory XII, third successor of Urban VI and now commonly considered the legitimate pope, and Benedict XIII, successor of the schismatic Clement VII, also generally regarded as an antipope. The principal task of the council, which opened on Nov. 5, 1414, at Constance in Baden, and closed on April 22, 1418, was to put an end to the great schism of the west. In this task it was successful. Other objects were the reform of the church and the examination of the teachings of John Wycliffe and John Huss.

Sigismund had persuaded John XXIII to call the council in a German city and had won for it the support of central Europe, England and most of Italy. The majority of the French episcopate and the University of Paris also favoured the council but the French government stood aloof. Scotland and the parts of Spain that remained true to Benedict XIII at first took no part in it.

The Council of Constance was a brilliant gathering. Thousands of persons, representing the intellect, learning and power of the age, thronged the streets of the little city on the Lake of Constance. At the time of its greatest numbers, it counted three patriarchs, 29 cardinals, 33 archbishops, 150 bishops, 100 abbots and 300 doctors of theology and canon law. If the staffs of the emperor and nobles, the retinues of the prelates and the merchants whom the council attracted are included, about 70,000 people attended, among them a large number who did not contribute to the council's good name.

The majority of the council's members acknowledged the Council of Pisa (1409) as ecumenical and considered John XXIII to be the legitimate pope. But when it was proposed that the decrees of Pisa, and implicitly the validity of John XXIII's election, be approved, the French cardinal Pierre d'Ailly intervened and maintained that all three contestants were obliged to obey the Council of Constance, which would decide who was the legitimate pope. The thesis that all three rivals should abdicate gained ground steadily. John XXIII hoped to maintain himself because he could count on the votes of the Italian bishops and prelates, who formed the majority of those with the traditional right of suffrage in ecclesiastical assemblies. The German members, however, were able to win the right of voting for the representatives of absent prelates, for doctors of theology and canon law and even for ambassadors of princes. This measure, which was against conciliar usage, broke the power of John XXIII. To decrease still further the influence of the Italians, it was decided that differences were to be settled not by the majority of those having right to vote but by nations, of which there were at first four: English, French, German and Italian. Later, the cardinals present were given a vote as a group, and still later, after the deposition of Benedict XIII, the Spanish nation was empowered to vote. This division according to nations, copied from the organization of the University of Paris, gave England, with a handful of representatives, as much power as Italy, with its great numbers.

John XXIII at first would not hear of abdicating, but under

threat of an investigation of his life, he promised on oath (March 2, 1415) to resign if his rivals would do the same. Three weeks later, however, he fled in disguise from Constance, hoping that this act would deprive the council of its authority and lead to its dissolution. The emperor, however, insisted that the council continue. D'Ailly and other leaders maintained that the popes were subject to the council. The consequence was that in the third session (March 29, 1415) and the fifth (April 6) the famous decrees on the church were passed. It was asserted that the council had its authority immediately from God and could not be dissolved or transferred by the pope without its consent; that everyone including the pope must obey the council in matters concerning the faith; the ending of the schism and the reformation of the church in head and members; and that the council had power to coerce and punish all the recalcitrants, even the head of the church.

It appears that these decrees, in the minds of those who voted them, applied not only to the Council of Constance, held in exceptional circumstances, but to all future councils. No pope and relatively few cardinals or bishops accepted this revolutionary interpretation of the church's fundamental law.

Four sessions of the council were devoted to an examination of the life of John XXIII, who had been brought back as a prisoner to Constance and who was deposed. Although he accepted the sentence, he was kept in captivity till 1418 by Sigismund and released only on the payment of a heavy ransom. He died in 1419.

In the 14th session (July 4, 1415), through a cardinal legate, Gregory XII convoked the council and ordered his adherents to join it. Then his free and unconditional abdication was announced. The council acknowledged this convocation and accepted the resignation. In gratitude for his resignation the council conferred on him the bishopric of Porto, the legation of Ancona and rank second only to that of the pope. He died in 1417. The council, after the convocation by Gregory XII, is regarded as a true general council by Roman Catholic theologians.

Benedict XIII refused to resign, although Sigismund went personally to his residence at Perpignan in France to persuade him. Sigismund, however, was able to induce the Spanish princes to abandon Benedict, who on July 26, 1417, was deposed by the council. He still refused to submit and remained in the castle of Peñíscola near Valencia till his death.

After the deposition of Benedict, the council decided that general councils were to be held frequently. One was to be held five years after the end of Constance, a second seven years later, and thereafter one was to be held every ten years. A disagreement about the order of procedure led to debate. Sigismund and the German nation wanted to proceed to a reform of the church before the new pope was elected. On Oct. 30, 1417, a decree was published binding the future pope to a reform.

In electing the new pope, the council decided that for this time 30 other prelates representing the different nations should be associated with the cardinals present at Constance. This concave on Nov. 11, 1417, elected Oddone Colonna, who became pope as Martin V.

The council also dealt with the teachings of John Wycliffe, John Huss and Jerome of Prague. Forty-five propositions of Wycliffe and 30 of Huss were condemned. Huss and Jerome were declared obstinate heretics, delivered to the secular arm and burned at the stake. (*See* further HUSS, JOHN; JEROME [OF PRAGUE].)

The council had also been summoned to bring about a reform of the church in head and members. Seven reform decrees were adopted and Martin V concluded concordats on other points chiefly methods of taxation, with the various nations. To the council's failure to effect any real reform the Reformation may in large part be attributed.

The Holy See never approved of the decrees of the council as a whole, and specifically reprobated those on the supremacy of the council. Others—*e.g.*, the condemnations of Wycliffite and Hussite doctrines—were accepted.

*See* PAPACY: *The Great Schism, 1378–1417: The Council of Constance; COUNCIL*. *See* also references under "Constance, Council of" in the Index volume.

(1896–1928); Hefele-Ledercq, *Histoire des conciles*, vol. vii, pp. 108–584 (1916); “Constance” in the *Catholic Encyclopedia*, vol. iv (1908); L. Christiani in *Dictionnaire de Droit Canonique*, vol. iv (1949). (E. A. R.)

**CONSTANCE, LAKE OF** (BODENSEE), after the lake of Geneva, the largest lake in the region of the Alps, lies along the northeast frontier of Switzerland with Germany and Austria. It is entered by the Rhine near Bregenz and the river leaves the lake at Stein am Rhein. The lower end of the lake is divided into two arms, the Untersee, below Constance, and the Überlingersee, extending to Ludwigshafen am Rhein. Lake Constance has an extent of 46½ mi. from southeast to northwest. Glacial in origin and hemmed in by moraines at its lower end, the lake lies 1,299 ft. above sea level, with a maximum width of 10½ mi. and a maximum depth of 827 ft. The area of the lake is 208 sq.mi., divided between Switzerland (cantons Thurgau and Sankt Gallen), Austria (Vorarlberg) and the Federal Republic of Germany. Bronze Age pile dwellings have been found and reconstructed at Meersburg, Ger. The island of Reichenau is the site of the medieval monastery of Zell.

See J. Früh, *Geographie der Schweiz*, 3 vol. (1930–45). (A. F. A. M.)

**CONSTANS, FLAVIUS JULIUS** (CONSTANS I) (c. A.D. 323–350), Roman emperor, was the fourth or fifth son of Constantine the Great. Proclaimed *Caesar* in 333, he became ruler of Italy, Africa and Illyricum on the death of his father (337). His brother Constantine II (q.v.) invaded northern Italy in 340, but was defeated and killed at Aquileia by the troops of Constans, who then became ruler of the western empire, Italy, Spain, Gaul and Britain. He defended his realm successfully against the Franks in 341, and in 343 visited Britain. He was an ardent Catholic, vigorously opposing Arianism (q.v.) and paganism. He was overthrown and killed in Gaul in 350 by Magnentius (q.v.). (E. A. T.)

**CONSTANS II** POGONATUS (630–668), Byzantine emperor from 641 to 668, became sole ruler in 641 after the death of his father, Constantine III, and the downfall of his uncle Heracleonas. He had to face the early onslaughts of Islam. Alexandria was finally lost in 646, and Egypt fell into Muslim hands. The Arabs, becoming powerful at sea, attacked Cyprus (649) and Rhodes (654). In 655 Constans was defeated at sea, and only internal dissensions prevented the Arabs from attacking Constantinople. They continually harried Asia Minor and gained a footing in Armenia. Constans ensured the defense of the eastern provinces by strengthening their military organization and was thus free to turn to the Balkans and the west. In 658 he campaigned against the Slavs who were settling in the Balkans. In 662 he took an army to Italy, visited Rome briefly in 663, and finally settled at Syracuse, intending to make it his capital. He evidently hoped to drive out the Lombards and had some success against them, but he then concentrated on consolidating the southern imperial provinces as a bulwark for protecting North Africa and Sicily against the Arabs. His heavy exactions led to an African revolt, but at least he contributed to the long persistence of Byzantine power in southern Italy and Sicily. He was assassinated at Syracuse on Sept. 15, 668.

Constans tried to impose unity on the church by an edict, the *Typus*, forbidding discussion of the monothelite question (648) and by the arrest, trial and exile of Pope Martin I (653). Both his foreign and his ecclesiastical policy show Constans to have been dominated by the old conception of a single universal empire comprising both east and west.

See G. Ostrogorsky, *History of the Byzantine State* (1956); E. W. Brooks in *Cambridge Medieval History*, vol. ii, ch. 13 (1913). (J. M. Hx.)

**CONSTANT, BENJAMIN JEAN JOSEPH** (1845–1902), French painter and etcher who gained particular fame for his portraits of the English aristocracy, was born in Paris on June 10, 1845. He studied under Alexandre Cabanel and greatly admired the work of Eugène Delacroix. In 1871 Constant traveled through Spain and Morocco, and the oriental subjects which this trip inspired established his reputation as a painter. Later he

turned toward more decorative painting for public buildings, and portraiture. He exhibited frequently in the Paris salons. As an occasional etcher, he is accredited with three plates.

**CONSTANT**, a quantity which does not vary. In mathematics and physics a quantity may be constant with respect to one variable but not with respect to another. Many so-called physical constants are constant under certain conditions only; e.g., the boiling point of a pure substance is constant only if the atmospheric pressure is constant (see VAPORIZATION). On the other hand there are constants which express invariable ratios, such as the gas constant *R* (see THERMODYNAMICS), the gravitational constant *G* (see GRAVITATION) and Avogadro's constant (*q.v.*) *N*. The elementary electric charge *e* (see ELECTRON) is an example of the invariable measure of a physical property. Planck's constant *h*, the elementary quantum of action, is probably the most important constant in quantum theory (see QUANTUM MECHANICS). Another famous physical constant is the velocity of light, approximately  $3 \times 10^{10}$  cm. per second (see LIGHT, VELOCITY OF; see also PHYSICAL UNITS).

See also references under “Constant” in the Index.

**CONSTANȚA**, a town of Rumania and administrative centre of the Dobruja region, is located on the Black sea, 201 km. (about 125 mi.) E. of Bucharest. It is the principal seaport of Rumania and, like Bucharest, has the status of a *regiunea* (region). Pop. (1966) 150,436. The first settlement on the site was the ancient city of Tomis, founded in the 6th century B.C. by Greek colonists. It was the place of exile of the Roman poet Ovid, and numerous remains testify to the existence of a flourishing Greco-Roman settlement of considerable military importance. In the 4th century the town was largely rebuilt by Constantine the Great and renamed Constantiana. Its modern development dates from the late 19th century.

The port and dockyards, rebuilt and modernized, are connected by oil pipeline to Ploesti. Air service is from Hellenie. There are brick, textile and edible-oil factories, slaughterhouses, flour mills and rice-husking plants. Constanța contains several theatres and a regional archaeological museum. The marine zoological station, directed by Iași university, carries on research on the marine biology of the Black sea. An aquarium is connected with it. Constanța is a popular seaside resort.

**DOBRUJA** (formerly Constanța) ADMINISTRATIVE AND ECONOMIC REGION is situated in the southeastern part of Rumania between the Danube and the Black sea, covering part of the historic territory of Dobruja (q.v.). Area 15,460 sq.km. (5,969 sq.mi.). Pop. (1960 est.) 502,674. It is divided into nine districts.

The relief of the region is formed of the Danube delta, the Măcin mountains, the Babadag and Dobruja plateaus and the Black sea coast. The climate is continental-temperate. The hydrographic network consists of lakes and rivers with a small and variable flow. A steppe vegetation prevails.

Minerals include copper, barite, iron ores, marble, limestone and chalk. Industry is concentrated in Constanța, Medgidia, Cernavodă, Năvodari and Tulcea and includes metallurgical, chemical, food-processing and thermal power plants. Agriculture, which is important in the region's economy, is completely collectivized. Wheat, maize, barley, oats and fruits are grown, and Constanța is the home of the Murfatlar wine. Merino sheep are bred on the Dobruja plateau. The region produces 70% of Rumania's fish catch, including both fresh- and salt-water varieties. There are a number of resort towns on the shore of the Black sea.

**CONSTANT DE REBECQUE, HENRI BENJAMIN** (BENJAMIN CONSTANT) (1767–1830), Franco-Swiss novelist and political writer, the author of *Adolphe* (1816), a forerunner of the modern psychological novel, was born at Lausanne, Switz., on Oct. 25, 1767, the son of a Swiss officer in the Dutch service, whose family was of French origin. The very type of the cosmopolitan European of the Napoleonic generation, he studied at Erlangen, Ger., briefly at Oxford, and at Edinburgh. In 1787 he formed, in Paris, his first liaison, with Madame de Charrière (q.v.), 27 years his senior. His republican opinions in no way suited him to the office of chamberlain to the duke of Brunswick, which he held for several years, marrying in 1789 a lady of the court, Baroness

Chamm. In 1794 he chose the side of the French Revolution in a divided Europe, abandoning both his office and his wife, whom he divorced. The influence of Madame de Staël (*q.v.*) had a good deal to do with his decision. He had met her at Lausanne earlier in 1794 and he accompanied her on her return to Paris in 1795 after the Terror. Their tumultuous and passionate relationship was to last until 1806. It corresponds with the first part of the political life of Constant who, throughout the period of the Directory, remained a faithful supporter of Barras. After the *coup d'état* of 18 Brumaire (1799) he was nominated a member of the tribunate, but he quickly became, like Madame de Staël, an opponent of the Bonapartist regime and, expelled from the tribunate in 1802, followed her into exile the year after. During the succeeding years he spent his time either at Madame de Staël's *salon* at Coppet, near Geneva, or in Germany, chiefly at Weimar, where he met Goethe and Schiller. Constant, among the most talented of those who transmitted German literary influence to France, was the associate, both at Coppet and in Germany, of the brothers Friedrich and August Wilhelm von Schlegel, the pioneers of the romantic idea, and with them he inspired Madame de Staël's book, *De l'Allemagne*.

This period of exile was the most productive in Constant's life. For many years he had been collecting material for the book on which he was now engaged, which was to be his life's work, *De la religion considérée dans sa source, ses formes et ses développements* (5 vol., 1824–31). It is a historical analysis of religious feeling in all its varied forms and also the argument of a positive, even a skeptical, nature confronting the threat of death. In it he revealed his inner self, as he also did in his intimate diaries, which for long remained unknown, in his correspondence—particularly with his cousin Rosalie—and not least in *Adolphe*, the barely disguised account of his break with Madame de Staël in 1806.

Nearly a century and a half after the appearance of *Adolphe*, another novel, *Cécile*, dealing with events between 1793 and 1808, was discovered. Constant has been compared as a novelist with Stendhal, and, in fact, beneath the romantic trappings and rapturous emotion, there is to be found the sure and easy artistry of a masterly prose writer, and the objective observation which belongs to a true storyteller and which makes him a pioneer of the psychological novel.

In 1808 Constant secretly married Charlotte von Hardenberg, whom he had known at Brunswick. But his intellectual relationship with Madame de Staël and the group at Coppet remained unbroken. This is confirmed in the preface (1809) to his mediocre adaptation—greatly admired by Madame de Staël—of Schiller's *Wallenstein*.

Nevertheless, Constant's principal ambitions were political. He published in 1813, in Hanover, *De l'esprit de conquête et de l'usurpation dans leurs rapports avec la civilisation européenne*, in which he surveyed the decadence of the Napoleonic regime. As a liberal he was, like Madame de Staël, disappointed by the Restoration, and he reconciled himself with the Empire of the Hundred Days under the influence of Madame Récamier, the other great love of his life. On his return to Paris after a short exile, Constant, through the *Minerve française* (1818) and *La Renommée* (1820), became one of the leaders of liberal journalism. He was elected a deputy in 1819 and advocated the liberty of the press. He collected his articles and speeches and published them as a sort of political testament. He died in Paris on Dec. 8, 1830, having seen the realization of the Staëlian political ideal: the monarchy of Louis Philippe brought about by the revolution of July 1830. On Aug. 27 of the same year he had been appointed president of the council of state.

Constant's complete works were published in 1957, edited by A. Roulin, who also edited the first edition of *Cécile* (1951; Eng. trans. by N. Cameron, 1952). There are numerous translations of *Adolphe* and of *Le Cahier rouge*, Constant's autobiography until 1787, which describes his travels in Britain.

**CONSTANTIA**, a valley and residential town on the Cape peninsula, Republic of South Africa, lies about 10 mi. S. of Cape Town by road. Pop. (1960) 15,556. The valley is famous for its wines, the finest of which are produced by the government wine farm of Groot Constantia and the adjacent farm of High Constantia. It produces especially the best light-bodied red table wines. The district is also renowned for its excellent fruits. Groot Constantia house, a fine example of a Dutch colonial manor house, has been restored and turned into a museum containing antique Cape furniture of stinkwood. It was built (c. 1685) by the governor Simon Van der Stel and named after his wife, Constance. Van der Stel also laid out the vineyard. In earlier times ship-masters and others visiting Cape Town would visit Groot Constantia where, after lavish entertainment by the proprietor, they frequently placed orders for wine.

**CONSTANTINE** (CONSTANTINUS), the name of a pope and an antipope.

CONSTANTINE (d. 715), pope from 708 to 715, upheld Roman supremacy against Ravenna's claim to independence. Summoned to Constantinople, probably to obtain his ratification of the Trullan council of 692, he was flatteringly received by Justinian II, who "renewed all the privileges of his church." After Justinian's murder (711), Constantine's conflict with the usurper Philippicus, a monothelite heretic, foreshadowed the iconoclast controversy. He died April 9, 715.

CONSTANTINE II, antipope from 767 to 768, was a soldier and brother of Toto, duke of Nepi, through whom, on the death of Paul I, he was elected pope on July 5, 767. His opponents, led by the powerful *primicerius* Christopher, fled to the Lombards. Constantine failed to win support from Pepin and the Franks. His deposition in 768 by a Lombard army was canonically ratified by a council of Italian and Frankish bishops; after 769 no more is heard of him.

See, for Constantine I, E. Caspar, *Geschichte des Papsttums*, vol. II, pp. 637–642 (1933); for Constantine II, L. Duchesne, *Les Premiers Temps de l'état pontifical*, new ed. (1912). (Hy. C.)

**CONSTANTINE**, the name of a number of Roman and Byzantine emperors.

CONSTANTINE I, called the Great (Flavius Valerius Constantinus) (d. A.D. 337), was the first Roman emperor attested to have become a Christian. He was born at Naissus (Nis) in Moesia, south of the lower Danube, on Feb. 17 of an unknown year, probably in the 280s, the eldest son of Constantius I (*q.v.*) by his first wife, Helena. When his father was given the title of Caesar in 293 Constantine was attached to the court of the emperor Diocletian, where he became tribune. He was present when Diocletian received an oracular response about the Christians, and must have witnessed the great persecution of 303. When his father received the title of Augustus for the western provinces of the Roman empire in 305, Constantine sought leave to join him, but Galerius, the eastern Augustus, would not let him go. He succeeded however in making his way to Gaul, and accompanied his father to Britain. When Constantius died at Eboracum (York), the troops proclaimed Constantine as Augustus on July 25, 306. Galerius grudgingly acknowledged him as Caesar, but when Maxentius, son of Maximian (*q.v.*), revolted in Italy (306), Constantine accepted his overtures, and Maximian, who had resumed the throne, granted him the title of Augustus and gave him his daughter Fausta in marriage on March 31, 307. Maximian soon quarreled with his son and sought refuge with his son-in-law; in 310, however, while Constantine was away on the Rhine, Maximian revolted at Arelate (Arles) but was quickly defeated and compelled to commit suicide. Constantine, whose claim to legitimate rule had been based on Maximian's recognition, now announced

that he was descended from the emperor Claudius II Gothicus and therefore claimed to rule by hereditary right, a claim going back beyond the emperor Diocletian and the rulers appointed by him. For portrait see article ROMAN HISTORY.

Constantine's ambition was not satisfied with being emperor of Gaul, and in 312 he invaded Italy, defeated Maxentius' generals near Augusta Taurinorum (Turin) and at Verona, and moving southward won the final victory over Maxentius in the battle of the Milvian bridge, where Maxentius was killed during the rout. Before this battle Constantine had a device representing the chi-rho monogram of Christ painted on his soldiers' shields, the first of his actions indicating conversion to Christianity. This monogram was later incorporated in the imperial standard, called the labarum.

Constantine was acknowledged by the senate as senior Augustus and accepted by all the western provinces. Next spring Licinius (q.v.), who ruled the dioceses of Moesia, Pannonia and Thrace, visited Constantine at Milan and married his sister Constantia. During the meeting Galerius Valerius Maximinus (q.v.), who ruled Asia Minor, Syria and Egypt, invaded Thrace, but Licinius hastened back and completely defeated him, thus becoming the sole ruler of the eastern provinces. On June 15, 313, he issued at Nicomedia (Izmit) an edict (often misleadingly called the edict of Milan) proclaiming the common policy, agreed between the two emperors at Milan, of full toleration for all religions and restitution of wrongs done to the Christians. Constantine himself went further, making lavish donations to the churches and granting immunities to the clergy.

**Conversion.**—The reasons for Constantine's conversion to Christianity have been much debated. Some believe that it was an astute stroke of policy, designed to win the support of the Christians, or a wise act of statesmanship aimed at buttressing the decaying fabric of the empire with the strength of the Christian church. Neither view is very likely, for the Christians, especially in the west, were a small and unimportant minority and the churches weak and divided.

Constantine's motives can be best divined from his voluminous letters and edicts on religion, whose authenticity has been proved. From these it appears that from 313 he regarded himself as the chosen servant of the "Highest Divinity" (whom he identified with the God of the Christians), who had given him victory over his enemies and raised him to supreme power, and believed that the prosperity of the empire and of himself, to whose care it had been committed, would be increased by God if his worship were properly conducted, and would be endangered if God were moved to wrath by its neglect.

This belief is most simply explained by the story Constantine himself many years later told his biographer Eusebius of Caesarea and confirmed upon oath. When he was contemplating his attack on Maxentius and considering whence he should obtain divine aid, he saw a cross of light superimposed upon the sun. This vision, whatever its nature, was decisive in his conversion, evinced in the favours he henceforth showered on the Christian church.

During the decade following his conversion Constantine's legislation shows many signs of Christian influence. For example, he repealed the legislation of Augustus that penalized celibates, legalized bequests to the church and gave full validity to manumission performed in a church. He even gave powers of jurisdiction to bishops, allowing either party to transfer a suit to the cognizance of a bishop, whose verdict should be final and executed by the civil authority. He also made Sunday a public holiday according to Christian practice, although he emphasized its sacredness to the sun. It was probably at this period that he built and lavishly endowed the Basilica Constantiniana and its baptistery, the Fons Constantini, in the palace of the Laterani in Rome.

**Religious Policy.**—Constantine was soon involved in ecclesiastical controversy, in particular that associated with Donatus (see DONATISTS). In 313 a group of African bishops led by Majorinus, who claimed to be bishop of Carthage, submitted to him charges against Caecilian, the rival bishop of Carthage, and asked him to appoint judges to decide the dispute. Constantine was already aware of the schism and on the suggestion of his ecclesiastical

adviser, Ossius, bishop of Córdoba, he had confined his benefactions to Caecilian's party, but he accepted the petition of the other group and appointed as judges the bishops of Rome, Arles (Arles), Augustodunum (Autun) and Colonia (Cologne). The bishop of Rome, having called in 15 Italian bishops in addition, pronounced in favour of Caecilian, but the defeated party, now led by Donatus, Majorinus' successor, appealed. Constantine summoned a larger council of bishops at Arles (314), and they again decided in Caecilian's favour. The Donatist party now appealed to Constantine himself. He eventually agreed to hear the case, and again condemned the Donatists. When they remained recalcitrant he endeavoured to suppress them by force, but they welcomed martyrdom. In 321 he ended the persecution, announcing that he would leave the dissidents to the judgment of God.

Constantine was convinced, doubtless by Ossius, that dissension in his church was deeply displeasing to God. It was the traditional duty of the emperor to maintain the *pax deorum*, and Constantine assumed that he had to win and retain for the empire the favour of God. He used the bishops as experts to pronounce on the religious issue, as his pagan predecessors had used the *pontifices* or the augurs, but he himself selected and summoned the bishops, received appeals on their decision and took what executive action he thought fit.

**Victory over Licinius and Foundation of Constantinople.**—Constantine and Licinius were soon at variance. In 314–315 there was a war in Pannonia in which Constantine on the whole gained the upper hand: Licinius had to cede to him the two dioceses of Pannonia and Moesia as the price of peace. In 317 Constantine's two elder sons, Crispus and Constantine, were jointly given the title of Caesar with Licinius' son Licinius, but relations gradually deteriorated. Licinius, uncertain of the loyalty of his Christian subjects, began to persecute them, and Constantine in a war against the Goths violated Licinius' territory in Thrace. In 324 Constantine attacked, and, fighting under the protection of the labarum, his armies were victorious at Adrianople (modern Edirne) in Thrace (July 3) and on Sept. 18 at Chrysopolis (Uskudar), situated opposite Byzantium across the Bosphorus. Licinius surrendered and in 325 he was executed for an alleged attempt at revolt.

Soon after his victory Constantine began to rebuild Byzantium on a magnificent scale, renaming it Constantinople (q.v.). He spent great wealth on his new foundation, and to adorn it robbed many pagan shrines of their statues and columns; the city was formally dedicated on May 11, 330. It symbolized a break with the pagan past which was identified with Rome, and heralded the beginning of a new Christian empire. Constantine states in one of his laws that he founded the new city "by the command of God," and he doubtless conceived it as a memorial and thank offering for the final victory whereby God had granted him rule over the whole empire. As such it was from the start a Christian city, unsullied by pagan sacrifice and amply endowed with magnificent churches. Coin types suggest that it was regarded as a sister to Rome, and it may have been called New Rome from the beginning. But it did not share Rome's constitutional privileges under Constantine. It had no prefect of the city until 359 and no senate, but was primarily an imperial residence.

**Arianism: Council of Nicaea and its Consequences.**—Immediately after his victory over Licinius Constantine had redressed the wrongs inflicted on the Christians during the recent persecutions and supplied funds for enlarging and rebuilding the churches in all the eastern provinces. He remembered from his youth that the church was far larger and more flourishing in the east than in the west, and he had hopes that the eastern bishops would be able to resolve the intractable Donatist problem. It was therefore with dismay that he discovered that the eastern churches were divided by a much more widespread dispute, the doctrinal controversy between Alexander, bishop of Alexandria, and one of his priests, Arius (see ARIUS; ARIANISM). Not understanding the theological points at issue Constantine first sent a letter to the two parties rebuking them for quarreling about minute distinctions, as he believed them to be, about the nature of Christ, and urging them to agree to differ, as did pagan philoso-

phers. Ossius, who carried this letter to Alexandria, soon discovered that the dispute was too serious to be thus resolved, and summoned a large council of Syrian bishops at Antioch (325). They condemned Arius, but before they had concluded their deliberations, Constantine decided to convoke a still larger council at Ancyra (Ankara) in Galatia. Shortly afterward he resolved to hold a universal (ecumenical) council of all the churches at Nicaea in Bithynia: this city was chosen as being more convenient for the bishops of Italy and the west who had been summoned, and for the emperor himself, who intended to be present. The Council of Nicaea met on May 20, 325. Constantine himself presided, actively guiding the discussions, and personally proposed (no doubt on Ossius' prompting) the crucial formula expressing the relation of Christ to God in the creed issued by the council, "of one substance with the Father" (see CREED). Overawed by the emperor, the bishops, with two exceptions only, signed the creed, many of them much against their inclination. The council also dealt with a number of lesser schisms and heresies, laying down the conditions on which their adherents might be readmitted to the church; endeavoured to settle the date of Easter; and regulated various questions of ecclesiastical precedence and organization. Constantine banished Arius and his partisans, confiscated the Arian churches and banned the cult of recusant schismatics and heretics.

Constantine regarded the decisions of Nicaea as divinely inspired. As long as he lived no one dared openly to challenge the creed of Nicaea, but the expected concord did not follow. Those who disliked the Nicene formula took every opportunity of attacking its principal adherents and succeeded in condemning several of them on charges of doctrinal error or uncanonical conduct. Their chief victim was Athanasius, who became bishop of Alexandria in 328 (see ATHANASIUS, SAINT). At first Constantine supported him, acquitting him of several charges, but he eventually lost patience. The emperor's cherished aim was to reconcile Arius with the church, but Athanasius stubbornly refused to accept Arius' vaguely worded submission. At last, in 335, Constantine summoned a council of bishops at Tyre to investigate various charges against Athanasius and ordered him to appear. The council condemned him; he appealed to Constantine himself, who banished him to Gaul. In the same year at a council at Jerusalem Arius was readmitted to communion.

During the last decade of his reign Constantine became increasingly pious. He devoted more and more of his time to completing his religious education, reading the scriptures and theological works supplied by Eusebius of Caesarea, listening to sermons and himself delivering homilies to his court. He continued to spend lavishly on building churches, at Rome, Constantinople, Antioch and the holy places in Palestine. He showed marked favour to Christians, thereby causing a flood of interested conversions. At the same time his attitude to his pagan subjects became more severe. Shortly after his victory over Licinius he issued an edict urging all his subjects to adopt the Christian faith, but at the same time he confirmed his policy of toleration to paganism (although in contemptuous language) and forbade overzealous Christians to disturb the pagan cult. He nevertheless destroyed three famous temples, at Aegae in Cilicia and at Apheca and Heliopolis in Phoenicia, and in 331 confiscated all the temple treasures, even stripping the cult statues of their gold; he probably also seized the temple endowments. Before the end of his reign he may even have banned sacrifice.

**Secular Policy.**—Much less is known of Constantine's secular than of his religious policy. He made an important change in the military organization of the empire, building up the *comitatus* (the imperial escort) into a large field army, partly by raising new regiments and partly by transferring to it the best units of the frontier armies. The *comitatenses* were accorded a privileged status and henceforth received the best recruits, and the frontier armies (*limitanei* or *ripenses*) thus sank in efficiency and morale. To command the *comitatenses* Constantine appointed two new officers, one in charge of infantry (*magister peditum*) and the other of cavalry (*magister equitum*). The praetorian prefects lost their military functions, and the separation of the military com-

mand from the civil administration, which the emperor Diocletian had begun, was thus completed. Unlike Diocletian, Constantine favoured the senate, appointing senators freely to provincial governorships and other administrative posts. He was also lavish in grants of senatorial rank, and initiated a great expansion of the senatorial order. He had a taste for pomp and ceremony, and revived or created many titles: he revived the ancient patriciate in a new form as a very select personal honour (see PATRICIANE), and in the order of the imperial "companions" (see COUNTESS) he created a new aristocracy of service, open to senators and non-senators alike. Constantine was of a lavish disposition, distributing gold and land on a vast scale to his favourites, and spending huge sums on his new capital and on benefactions to the churches. As a result of his extravagance he had to institute new taxes, the *collatio glebalis* or *foliis*, a surtax on senators, and the oppressive *collatio lustralis*, a levy of gold and silver on traders and craftsmen. The confiscation of the temples eased the financial strain at the end of his reign, enabling him to mint large quantities of gold and silver coins. His gold coin, the solidus, which he minted from the beginning of his reign at 72 to the pound, was maintained for many centuries at its original weight and purity.

Constantine was a firm believer in the principle of hereditary succession, and gave his sons the title of Caesar (Crispus and Constantine in 317, Constantius in 324 and Constans in 333, as well as a nephew, Dalmatius, in 335) and allotted them parts of the empire to govern. Crispus (see CRISPUS CAESAR) was executed in mysterious circumstances in 326. The others at the end of the reign shared the government of the whole empire between them, the young Constantine ruling Britain, Gaul and Spain, Constans Italy, Africa and western Illyricum, Dalmatius Thrace, Dacia and Macedonia, and Constantius the eastern provinces (Asia and Egypt). Constantine could thus concentrate on his religious duties. In the spring of 337 he fell seriously ill at Nicomedia and received baptism from Eusebius, bishop of Nicomedia, an Arian. A few days later, on May 22, he died at Ancyrona, near Nicomedia.

Constantine hardly deserves the title of "the Great"; he was an able general but lacked other qualities of a good emperor. He was extravagant, susceptible to flattery, and capricious. His temper was violent, but he was easily mollified and he lacked firmness and steadiness of purpose. Still less does he deserve the title of saint, which he holds in the Orthodox Church. His dominating passion was ambition, and he was unscrupulous and ruthless to his rivals. His religious beliefs, though sincere, were perhaps vague. For instance, for some years after his conversion he continued to issue coins in honour of "the Unconquered Sun." He may at first have believed, as his vision might suggest, that Christ and the sun were both aspects of "the Highest Divinity." Nevertheless his reign was of immense importance for the future of the empire, of the church and of Europe. Constantinople, which he probably founded as a memorial of his final victory, sustained and inspired the empire for more than a millennium. The manner of his conversion influenced the relations of church and state for centuries to come. Believing that he was God's chosen servant he regarded himself as responsible to God for the good government of his church. Above all his conversion assured the future of Christianity. From a minority sect Christianity became the official religion of the empire and was stimulated by the imperial patronage of Constantine and his sons. The church so grew in wealth and numbers that its position could not be shaken by the apostate emperor Julian. (See also references under "Constantine I [the Great]" in the Index volume.) (A. H. M. J.)

CONSTANTINE II (317–340), Roman emperor, second son of Constantine the Great, was born at Arles (Arles) in Feb. 317 and on March 1, 317, was given the title of Caesar. After the death of his father in 337 he became ruler of Britain, Gaul and Spain. At first he tried to control his brother Constans (q.v.), who soon objected. Constantine claimed Italy and Africa from him, and early in 340 unexpectedly attacked Italy and penetrated to Aquileia. There he was met by the vanguard of the army of Constans, who was then at Naissus (Nis) in Moesia, and was killed. (E. A. T.)

CONSTANTINE III (612-641), Byzantine emperor in 641, son of the emperor Heraclius by his first wife, Fabia-Eudocia, succeeded as joint emperor with Heracleonas, the son of Heraclius by his second wife, Martina. Court intrigues nearly led to a civil war, which was prevented by the death of Constantine (May 641). It was rumoured that he was poisoned by order of his stepmother, but he probably died of tuberculosis.

CONSTANTINE IV, Byzantine emperor from 668 to 685, was the eldest son of Constans II. He took a decisive stand against the Arabs under the caliph Mu'awiya. From 674 onward they besieged Constantinople until their decisive defeat in 678, which greatly enhanced Byzantine prestige and indeed marked a turning point in European history. In the Balkans Constantine campaigned against the Slavs and Avars and repulsed their attack on Thessalonica, but he could not prevent the Bulgars from crossing the Danube and establishing their kingdom in the district where their name still survives. He had to recognize them and pay annual tribute. Constantine summoned the sixth ecumenical Council of Constantinople (680-681), which condemned monotheletism and recognized the orthodox christological doctrine as laid down by the Council of Chalcedon (451).

CONSTANTINE V Copronymus (718-775), son of Leo III the Iconoclast, of the "Isaurian" or North Syrian dynasty, was Byzantine emperor from 741 to 775. Soon after his accession, while he was fighting against the Arabs, his brother-in-law Artabasdos, the count of the Opsikion theme, who opposed iconoclasm, set up as rival emperor. It was not till toward the end of 743 that Constantine finally defeated Artabasdos and re-entered Constantinople. When he felt his position secure, he determined to settle the religious controversy. In 754 he called a synod of 338 bishops at the palace of Hieria across the Bosphorus from Constantinople, and the veneration of icons was forbidden. But resistance to iconoclasm continued, partly owing to the influence of the monks, against whom a vigorous campaign was undertaken. Constantine was an able military commander. He invaded northern Syria, and won a naval victory against the Arabs (747). He then advanced into Armenia and Mesopotamia. He did not succeed in holding these areas, but he had checked the Arabs and prepared the way for the Byzantine offensive in the following century. In the Balkans he warred continually against the powerful Bulgarian kingdom, finally dying on campaign, Sept. 14, 775.

These life and death problems had given Constantine little time for Italy, where the Byzantine position was being undermined by the Lombards; the pope (who had hitherto maintained his loyalty to Constantinople while protesting vigorously against iconoclasm) turned to the Frankish rulers for help. Henceforth the links between Italy and Constantinople were weakened and Byzantine authority confined to its provinces in south Italy. Constantine was blackened by the Orthodox historians of his time, but modern scholars have recognized that he was one of the most capable of the Byzantine rulers.

CONSTANTINE VI (770-after 797), grandson of Constantine V, was Byzantine emperor from 780 to 797. At ten years of age he succeeded his father, Leo IV, under the guardianship of his mother, Irene (q.v.). It was during her regency that the seventh ecumenical Council of Nicaea (787) re-established the veneration of icons. When Constantine came of age Irene attempted to retain supreme power, but in 790 the army proclaimed Constantine VI as sole ruler and she was arrested. Constantine foolishly pardoned her in 792. In 796 Constantine roused public opinion by divorcing his wife in order to marry his mistress, Theodote. Irene cleverly utilized this situation and in Aug. 797 had Constantine blinded. He was the last of the "Isaurian," or North Syrian, dynasty.

CONSTANTINE VII Porphyrogenitus ("born in the purple") (905-959), Byzantine emperor, author and patron of literature, was the son of Leo VI the Wise. Though nominally emperor from 913 to 959, he was in practice excluded from all real share in the government until 945, after his father-in-law, Romanus I Lecapenus, had been exiled in 944. He continued the latter's policy of supporting the small farmer and safeguarding the soldiers' holdings, and of waging war against the Arabs in the east Mediterranean. He also maintained diplomatic relations with foreign

countries, and in 957 received a state visit from the Russian princess Olga who had recently been converted to Christianity.

Constantine is best known for his patronage of art and literature, and he was well versed in the traditions of classical antiquity. Valuable information about the Byzantine empire is supplied by the works written by him or directly inspired by him. His own works are: *De thematibus*, a geographical and historical account of the Byzantine provinces; *De administrando imperio*, a handbook for the foreign office, written for his son, Romanus II; *De cerimoniis aulae byzantinae*, on customs and ceremonial of the Byzantine church and court with much historical and archaeological material; a life of Basil I, his grandfather, forming book v of the history known as *Theophanes Continatus*. Under his auspices a number of works of an encyclopaedic nature were compiled, consisting of excerpts from classical and later authors. A number of manuscripts of the more complete works of classical authors date from this period.

CONSTANTINE VIII (958-1028), Byzantine emperor, the younger brother of Basil II and coemperor 976-1025, sole ruler 1025-28. He was a pleasure-loving man who allowed the administration to fall into the hands of others. He had no male heir and on his deathbed he arranged that his second daughter, Zoe, should succeed him and marry the eparch of Constantinople, Romanus III Argyrus.

CONSTANTINE IX Monomachus (c. 980-1055), Byzantine emperor from 1042 to 1055, owed his elevation to Zoe, the empress of the Macedonian dynasty who took him as her third husband. Constantine belonged to the civil party, the opponents of the military magnates, and he neglected the defenses of the empire and reduced the army. He spent extravagant sums on luxuries and magnificent buildings and seriously debased the coinage. Rebellions broke out at home and abroad; the Normans were overrunning the Byzantine possessions in south Italy; the Pechenegs (Patzinaks) crossed the Danube and attacked Thrace and Macedonia; and the Seljuk Turks made their appearance on the Armenian frontier which was directly exposed to attack, as the Armenian kingdom of Ani lapsed to Constantinople during this reign. Constantine attempted to ally with the papacy against the Normans, but relations between the churches of Rome and Constantinople deteriorated, and in 1054 the visit of the papal legates resulted in schism. Though he was not outstanding for his statesmanship, it was under his auspices that the university of Constantinople was reorganized, and there was a marked efflorescence of learning and letters.

CONSTANTINE X Ducas, Byzantine emperor from 1059 to 1067, succeeded Isaac I Comnenus. His accession was a triumph for the civil aristocracy but was unfortunate in that he proved an incapable emperor. He reduced the army and neglected the frontier defenses at a time when the Seljuk Turks were pressing into the eastern provinces; and the sultan Alp Arslan overran Armenia (1064-65) and attacked Caesarea (1067). In 1064 the Hungarians occupied Belgrade, and the Pechenegs (Patzinaks) and Uzes (Kumans) crossed the Danube and ravaged the Balkan provinces, penetrating into Greece. In Italy the Normans were rapidly conquering the last remnants of the Byzantine possessions.

(J. M. Hv.)

CONSTANTINE XI (Constantine Dragases Palaeologus) (1404-1453), the last Byzantine emperor (1449-53), was the fourth son of the emperor Manuel II and his Serbian wife, Helen, of the dynasty of Dragas in Macedonia. He spent his early career with his brothers Theodore and Thomas governing the Byzantine despotate of the Morea (Peloponnese) and completing its recovery from the Franks; and when his brother John VIII died childless in 1448 he was proclaimed emperor at Mistra (Jan. 1449). He was a man of courage and energy, but he succeeded to a *damnsa hereditas*. Mohammed II, who became Ottoman sultan in 1451, directed all his resources to the capture of Constantinople. Constantine did everything within his power to organize the defense of the city and to enlist the support of the west by acknowledging the obedience of the Greek church to Rome, but in vain. He was killed fighting at the walls when the Turks finally broke through on May 29, 1453.

(D. M. N.)

**BIBLIOGRAPHY.**—*Constantine the Great*: The principal contemporary literary sources for Constantine's reign are his laws, preserved in the *codex Theodosianus*; the *De mortibus persecutorum* of Lactantius Firmianus; the last books of Eusebius' *Ecclesiastical History*; Eusebius' *Life of Constantine*, now generally admitted to be a genuine work left unfinished by its author and posthumously edited; and Athanasius' *The Defense Against the Arians*. There are also a number of ecclesiastical documents, including imperial letters, preserved in these and later histories and collections. Of the later writers Socrates, Sozomen and other ecclesiastical historians give a flattering picture, the pagan Zosimus a very hostile one. Modern studies include N. H. Baynes, *Constantine the Great and the Christian Church* (1931); A. Piganiol, *L'Empereur Constantin* (1932); A. H. M. Jones, *Constantine and the Conversion of Europe* (1948); J. Vogt, *Constantin der Grosse und sein Jahrhundert* (1949). (A. H. M. J.)

*Constantine III-VI*: J. B. Bury, *History of the Later Roman Empire*, vol. II (1889); G. Ostrogorsky, *History of the Byzantine State* (1956).

*Constantine VII*: Works ed. by I. I. Reiske and I. Bekker in the Bonn corpus (1829-40) and in J. P. Migne, *Patrologia Graeca*, vol. cxlii-cxliii (1864); *De administrando*, ed. by G. **CONSTANTINE (FLAVIUS CLAUDIUS CONSTANTINUS)** (d. A.D. 411), usurper of the title of Roman emperor A.D. 407-411, was recognized as emperor by Flavius Honorius (q.v.) in 409. A private soldier elevated by the army in Britain in 407, he immediately crossed to the continent with a force of British troops, who feared that the invasion of Gaul by the Vandals and other barbarians, which had begun in 406, would lead to an attack on Britain. By the end of 407 he possessed eastern Gaul and defeated the invaders. The central government sent a force against him commanded by a Goth called Sarus, who defeated Constantine's generals and besieged the usurper in Valentia (Valence). But Sarus had to retire (408), and Constantine established himself at Arles (Arles). The Roman troops in Spain joined him, and Constantine, appointing his son Constans as *Caesar*, sent him with Gerontius as master of the soldiers to suppress a revolt organized there by relatives of Honorius. After the fall of Stilicho (q.v.) in 408 Constantine threatened Italy, and Honorius was obliged to recognize him as joint emperor (409). Constans, successful in Spain, returned to Gaul; but Gerontius and the troops in Spain set up one Maximus as a rival emperor, which seriously weakened Constantine and later led to the defeat and death of Constans at Vienne (c. 411). Constantine entered Italy, but he had to retreat to Arles, where he was besieged by Honorius' generals; he capitulated and was killed in Sept. 411. (E. A. T.)

**CONSTANTINE**, kings of the Hellenes. They are numbered either I and II, as sovereigns of the modern kingdom of Greece, or XII and XIII, as theoretical successors, to some extent at least, of the Byzantine emperors. (The Greek word *basileus*, "king," can also mean "emperor.")

**CONSTANTINE I or XII** (1868-1923), king from 1913 to 1917 and from 1920 to 1922, was born in Athens on Aug. 2, 1868, the eldest son of King George I (q.v.) and his consort, the Russian grand duchess Olga Konstantinovna. His education was completed in Germany (from 1886), at Leipzig University and at the Prussian Military Academy; and in 1889 he married Sophia, sister of the German emperor William II. In the Greco-Turkish War of 1897 the forces under Constantine's command in Thessaly were defeated, but in 1900 he was nonetheless made commander in chief of the Greek Army. The Military League insisted on his retirement from the army after the failure to achieve union with

Crete in 1909, but Eleutherios Venizelos (q.v.) procured his return, as inspector general, in 1911. While successes in the Balkan Wars of 1912-13 were restoring Constantine's popularity, his father was assassinated (March 18, 1913), and he became king.

In World War I the king, pro-German, wanted to keep Greece neutral, whereas Venizelos stood for a pro-Allied policy. For the progress of the dispute, exacerbated by the Anglo-French occupation of Salonika, by Bulgaria's attack on Serbia, and by the Greek royalists' surrender (May 1916) of a key position in Macedonia to the Bulgars, see *GREECE: History*. Venizelos set up a government of his own at Salonika in October 1916, and the Allies, pressing Constantine to reduce the potential threat of his forces to theirs in Macedonia, landed at the Piraeus on Dec. 1. They were repulsed, but an Allied ultimatum of Dec. 31 was backed by a naval blockade which compelled the king to agree to their demands. Venizelos still denounced the king as pro-German, and in June the Allies demanded his abdication. On June 12, 1917, without renouncing all his rights, he made his powers over to his second son, Alexander, and retired to Switzerland with his eldest son, George (who was not acceptable to Venizelos).

In 1920 Alexander died; his younger brother, Paul, refused the succession; and Venizelos fell from power. Despite the Allies' remonstrances, a plebiscite (Dec. 5) by a vast majority recalled Constantine to the throne. He felt himself obliged, however, to pursue the anti-Turkish policy in which Venizelos had had British support (see *GRECO-TURKISH WAR* [1921-22]), and the defeat of the Greeks in Anatolia brought his downfall. A military revolt broke out, and on Sept. 27, 1922, he abdicated in favour of his eldest son. He died in exile at Palermo, Sicily, on Jan. 11, 1923.

**CONSTANTINE II or XII** (1940- ), king from 1964, was born at Psychiko, near Athens, on June 2, 1940, the son of the future king Paul I (q.v.) and his consort, Frederika of Brunswick. He became crown prince in 1947 when his father succeeded to the throne. He represented Greece at the Olympic Games in Rome in 1960 and won a gold medal for yachting. He was proclaimed king on March 6, 1964, in succession to his father. On Sept. 18, 1964 Constantine married Anne Marie, daughter of Frederick IX of Denmark; an heir to the throne, the couple's second child, was born in May 1967. The king's choosing of successive premiers in 1965-66, after the dismissal of Georgios Papandreou, was criticized by leftists as "ruling" instead of merely "reigning"; but the military coup of April 1967 which suspended the parliamentary regime was executed without his foreknowledge, and his dealings with the new regime were marked by cautious reserve. See also *GREECE: History*.

**CONSTANTINE (KONSTANTIN PAVLOVICH)** (1779-1831) Russian grand duke, was born at Tsarskoe Selo (Pushkin) on May 8 (new style; April 27, old style), 1779. He was the second son of the emperor Paul I and his wife Maria Fedorovna, and the brother of Alexander I and Nicholas I. His grandmother, Catherine the Great, directed his education; the only person who really took him in hand was his tutor in chief, Frédéric César de La Harpe. Like Alexander, Constantine was married by Catherine when still in his teens, and he made his wife, Juliana of Coburg intensely miserable. After a first separation in 1799, she went back permanently to her German home in 1801.

Constantine's first military campaign took place in Italy in 1799 under the leadership of A. V. Suvorov during the war of the second coalition against France. The battle of Bassignano was lost by Constantine's fault, but at Novi he distinguished himself by such personal bravery that Paul I bestowed on him the title of tsarevitch (which properly belonged only to the heir to the throne). During the campaign of 1805 Constantine was in command of the guards and shared responsibility for the defeat in the battle of Austerlitz. In these and subsequent campaigns (1807, 1812, 1813 and 1814) he showed courage but no military competence.

The congress of Vienna made Poland a constitutional monarchy (known as Congress Poland) with the Russian emperor as king. Constantine's importance in political history dates from Nov. 1815, when Alexander I made him commander in chief of the Polish armed forces with powers so wide that he was in fact a viceroy. Constantine organized the Polish army and felt himself

more a Pole than a Russian, especially after hismorganatic marriage to a Polish lady, Joanna Grudzinska, on May 24 (N.S.; 12, O.S.), 1820. He himself renounced any claim to the Russian imperial succession (Aug. 28 [N.S.; 16, O.S.], 1823), but this was only revealed to three or four persons and his brother Nicholas was left in ignorance of it. As a result, on the death of Alexander I (Dec. 1 [N.S.; Nov. 19, O.S.], 1825), there was some uncertainty. Since the second half of the 18th century a revolutionary movement seeking some degree of self-government had been developing. The confusion surrounding the succession provided the revolutionaries with an opportunity for action, and on Dec. 26 (N.S.; 14, O.S.), the Decembrists (*see* DEKABRISTS) mutinied, demanding "Constantine and Constitution." The rising was easily suppressed, and Constantine had had no part in the plot, but differences soon arose between him and Nicholas I in consequence of the share taken by the Poles in the conspiracy. Constantine held obstinately to the belief that the Polish army and bureaucracy were loyally devoted to the Russian empire. Nicholas I's eastern policy and the Turkish War of 1828-29 caused a fresh breach between the brothers. It was due to Constantine's opposition that the Polish army took no part in the war.

Although Constantine had built up the army of Poland, he had failed to win its loyalty, and his harsh rule, in spite of his sympathy for Polish autonomy, had alienated the parliament and the people. The insurrection in Warsaw in Nov. 1830 took Constantine completely by surprise. Because of his utter failure to grasp the situation the Polish regiments passed over to the revolutionaries; and as the revolution wore on, he showed himself as incompetent as he was lacking in judgment. He did not live to see the rising suppressed, for he died of cholera at Vitebsk on June 27 (N.S.; 15, O.S.), 1831. (G. A. LN.)

**CONSTANTINE THE AFRICAN** (c. 1020-1087), an important medieval medical figure who initiated the translating of important writings from Arabic into Latin. His name is surrounded by legends and his early career is still obscure.

Although it is said that he was born at Carthage, his actual birthplace seems to have been Sicily, whose residents then spoke many tongues. It is certain that he was a Christian, knew Arabic as well as some Latin and Greek and led a wandering life. About 1071 he was in the service of the Norman duke Robert Guiscard, whom he probably followed to Salerno, the city with which Constantine's name is most closely linked. There he became a monk and ended his days at the Benedictine house of Monte Cassino, where he translated a number of Arabic works into Latin. His labours are exceedingly important for the history of culture. They represent the first inflow of a group of new ideas, and their appearance marks the end of the "dark ages" and the dawn of the scholastic period.

Among the works that Constantine thus conveyed were two philosophical treatises by Isaac Israeli (855-955) of Kairouan, known to the west as Isaac the Jew. The most important medical work that he translated into Latin he called *Pantechne*, an abbreviated version of the *Liber Regius* of the Persian Ali ibn al-Abbas (died 994), also known as Haly Abbas. This was extremely important as the first work that gave the western world a view of Greek medicine as a whole.

Constantine's translations spread through Europe with extraordinary rapidity and it is difficult to overestimate their influence on the ages that followed. They continued to be read until the sixteenth century and were particularly influential at the important medical school at Salerno.

*See* C. and D. Singer, "The Origin of the Medical School of Salerno" in *Essays on the History of Medicine Presented to K. Sudhoff* (1924); K. Sudhoff in *Kurses Handbuch der Geschichte der Medizin*, 4th ed. (1922). (C. SL; I. V.)

**CONSTANTINE** (anc. CIRTA), a city of Algeria, Africa, and capital of the prefecture of the same name, is 54 mi. S.S.W. of the port of Philippeville by rail. It is the seat of a bishop and a military station. Pop. (1960) 217,000 (metropolitan). The city occupies a rocky, diamond-shaped plateau, surrounded, except at the southwest, by a precipitous ravine through the eastern side of which flows the Rummel river. The plateau is 2,130 ft. above

sea level and from 500 to nearly 1,000 ft. above the river bed. The cliffs of the ravine, at its narrowest, are 15 ft. apart and at its greatest width, about 400 yd. The gorge is crossed at the northeast angle of the city by the El Kantara bridge, a modern 420-ft. structure constructed on the site of earlier bridges, and north and south by a suspension bridge and a viaduct, built in 1912. On the northeastern side it is spanned by natural stone arches.

**The City.**—Constantine is walled, the existing medieval wall having been largely constructed out of Roman material. Through the centre from northeast to southwest runs the Rue de France-Rue Caraman, roughly dividing the city into two parts. To the west are the kasbah (citadel), cathedral, prefecture building, town hall, law courts and other administrative and commercial buildings, standing among straight streets and wide squares. The east and southeast part provides a striking contrast, with its tortuous lanes and oriental architecture. The Place de Nemours, at the southwest, is the commercial and social centre, and from it the Rue Georges Clemenceau, with some commercial offices, runs northeast to the El Kantara bridge, which leads to the railway station. The palace of Haji Ahmet, built in 1830-35 by the last bey of Constantine and subsequently in military use, stands on the Place Maréchal Foch, as does the cathedral, once the mosque of Souk el Ghezal. The massive kasbah, containing barracks and a hospital, occupies the northern apex of the city. It dates from Roman times and in its more modern portions preserves remains of other Roman structures. The mosque of Sidi el Kettani (or Salah Bey), on the Place Négrier southeast of the kasbah, and that of Sidi Lakhdar farther southeast date from the 18th century. The city has *lycées* for boys and girls, a technical college and a Franco-Muslim *lycée* (*medersa*). There are a museum and library, a theatre, a casino and sports stadiums. New quarters have been developed southwest of the town.

The industry of Constantine is chiefly confined to leather goods and woolen fabrics. A considerable trade is carried on over a large area through the town's railway connections with Algiers, Bône, Tunis, Biskra and Philippeville.

**History.**—Constantine or, as it was originally called, Cirta or Kirtha, from the Phoenician word for city, was one of the most important towns of Numidia (q.v.) and the residence of the kings of the Massyli. Under Micipsa (2nd century B.C.) it reached the height of its prosperity and was able to furnish an army of 10,000 cavalry and 20,000 infantry. Julius Caesar having bestowed a part of its territory on his supporter Sittius, the latter introduced a Roman settlement. In the war of Maxentius against Alexander, the Numidian usurper, it was laid in ruins, and on its restoration in A.D. 313 by Constantine it received its present name. It was not captured during the Vandal invasion of Africa but on the Arab conquest (7th century) it shared the fate of the surrounding country. Successive Arab dynasties looted it. During the 12th century it was still prosperous, however, and its commerce was extensive enough to attract the merchants of Pisa, Genoa and Venice. Frequently taken and retaken by the Turks, Constantine became the seat of a bey, subordinate to the dey of Algiers. Salah Bey, who ruled from 1770 to 1792, was responsible for most of the existing Muslim buildings. In 1826 Constantine asserted its independence of the dey of Algiers and was governed by Haji Ahmed, the choice of the Kabyles. In 1836 the French under Marshal Bertrand Clauzel made an unsuccessful attempt to storm the city, suffering heavy losses. In 1837 Marshal S. C. Valée took it by assault from the southwest isthmus. In World War II, during the 1942-43 Allied campaign against the Axis, Constantine and nearby Sétif were important bases and centres of command. (X.)

**CONSTANTINE TERRITORY**, formerly the eastern of the three *départements* of northern Algeria, and from 1956 to 1958 a regional prefecture, comprises the four *départements* of Constantine, Bône, Sétif and Batna. It covers the whole of eastern Algeria, a countryside of mountains and plateaus, culminating in the Aurès mountains (7,638 ft.) in the south. Despite unpropitious terrain the population is dense and includes considerable elements retaining the Berber language and customs. Pop. (1960) 3,815,000, including

about 175,000 Europeans. Area 39,060 sq.mi. The territory has a territorial assembly, with prefects in charge of each *département*. See E. Mercier, *Histoire de Constantin* (1905). (A. B. M.)

**CONSTANTINOPLE**, the capital of the Byzantine empire (*q.v.*) until its fall to the Turks in 1453 and then of the Ottoman empire (*see* TURKEY), is now called Istanbul (*q.v.*) and was originally Byzantium (*q.v.*). When Byzantium, on the European shore of the Bosphorus, was officially inaugurated as the new capital in 330 by the emperor Constantine I (*q.v.*), it bore the names of New Rome and of Constantinopolis, after its founder. When the new Turkish republic succeeded the Ottoman empire in 1923, Constantinople ceased to be the capital city. In 1930 it was officially renamed Istanbul, as it had long been popularly called. The old name survives, however, in the title of the ecumenical patriarch of Constantinople, who still has his seat in Istanbul (*see* CONSTANTINOPLE, ECUMENICAL PATRIARCHATE OF). For the church councils held in Constantinople, *see* COUNCIL.

**CONSTANTINOPLE, ECUMENICAL PATRIARCHATE OF**, one of the four ancient autocephalous patriarchates of the Greek Orthodox Church federation (the others being Antioch, Alexandria and Jerusalem) and during the great period of the Byzantine empire the most powerful of all; before the division of the church the ecumenical patriarch ranked second only to the bishop of Rome among all the bishops. He retains his spiritual authority over the other Orthodox churches, though his actual jurisdiction has been much curtailed since Turkey became almost entirely Muslim and the national churches of many regions formerly subject to him gradually have become autocephalous.

**History.**—According to a legend of the late 4th century, the bishopric of Byzantium was founded by St. Andrew, whose disciple Stachys, mentioned in the New Testament as a friend of St. Paul (Rom. xvi, 9), was traditionally the first bishop (38–54). Soon after Constantine the Great in 330 transferred the capital of the Roman empire from Rome to Byzantium, renamed Constantinople and New Rome, its bishopric was elevated to an archbishopric. The metropolitan of Heraclea, to whom Byzantium had formerly been subject, now came under the jurisdiction of Constantinople, with the privilege of handing the bishop his crosier at his enthronement. The third canon of the second ecumenical Council of Constantinople (381) recognized that the bishop of Constantinople, "being now the New Rome," had rights equal to those of the bishop of Rome. This position was ratified by the 28th canon of the fourth ecumenical Council of Chalcedon (451), which assigned to his jurisdiction a large area in both eastern Europe and Asia Minor. In the 6th century the official title of the bishop became "archbishop of Constantinople, New Rome, and ecumenical patriarch"; the exact significance of "ecumenical patriarch" has never been officially defined. The successful territorial conquests of the Muslims, beginning in the 7th century, helped to augment the spiritual power of the ecumenical patriarchate. The patriarchs of the conquered sees were often forced into exile and became residents of the capital, where their successors over a long period were selected by the ecumenical patriarch.

The exaltation of Constantinople was not agreeable to Rome, yet the ecumenical patriarch never claimed to be a rival of the bishop of Rome. In the 9th century the two great sees were divided by the schism over the patriarch Photius (*q.v.*). Although this was temporarily healed, theological and political differences continued until in 1054 the final break was made under the patriarch Michael Cerularius.

After the capture of Constantinople by the Latins in the fourth crusade (1204), the ecumenical patriarchate was transferred to Nicaea (1206). It was restored to Constantinople when the emperor Michael VIII Palaeologus retook the city in 1261. In 1453 Constantinople fell to the Turks and the city became the capital of the Muslim Ottoman empire.

Constantinople has played an important role in church history. As the see of the capital of the Byzantine empire it was the centre of the theological controversies in which, from the 4th century on, the doctrines of the Holy Trinity and of the Person of Christ were finally formulated. Three of the ecumenical councils recognized by both Eastern and Western churches were held in Con-

stantinople (*see* COUNCIL), and the first of these (381) promulgated the Niceno-Constantinopolitan Creed, commonly known as the Nicene Creed (*see* CREED). Constantinople was a great centre for monasticism, one of its chief houses being that of Studios, whose monks were fierce opponents of iconoclasm (*see* ICONOCLASTIC CONTROVERSY). The profoundly religious art of the Byzantine empire was largely produced in Constantinople under the inspiration of the church (*see* BYZANTINE ART).

A list of the patriarchs of Constantinople includes a number of famous names. The great theologian Gregory of Nazianzus (*q.v.*) one of the three Cappadocian Fathers, was bishop of Constantinople briefly in 381. John Chrysostom (*q.v.*), the most famous preacher among the Greek Fathers, was bishop from 398 to 404. Nestorius (*q.v.*) was bishop for three years before being deposed at the Council of Ephesus (431) for his christological teaching. The 6th-century patriarch John III Scholasticus was learned in canon law. Photius, one of the most distinguished Byzantine scholars of any period, was primarily responsible for the mission of SS. Cyril and Methodius to the Slavs. Jeremy II corresponded with Pope Gregory XIII about calendrical reform and held discussions with the Protestant theologians of Tübingen. In the 17th century Cyril Lucaris (*q.v.*) became involved in Calvinistic disputes. Gregory V was martyred by the sultan during the Greek War of Independence (1821).

**Jurisdiction.**—After the fall of Constantinople the ecumenical patriarch (Gennadius II) was recognized as the ethnarch of the conquered Orthodox peoples, with increased authority over the territories of the eastern patriarchates and over the Balkan countries as well as farther afield. This power began its decline when Jeremy II declared the patriarchate of Moscow autocephalous (1593), and was continued in the 19th and 20th centuries when various other national churches in Orthodox territories became in their turn autocephalous. A further reduction in the number of dioceses subject to the patriarch was caused by the exchange of populations in 1922, when about 1,500,000 Greek inhabitants of Asia Minor and Thrace were transferred to Greece, whose church had been autocephalous since 1833. This meant that there were practically no Christians left in Asia Minor.

The territory directly subject to the patriarch in Turkey is confined to the archdiocese of Constantinople itself, together with the four suburban dioceses of Chalcedon, Derkon, Pringiponissos and the islands of Imroz (Imbros) and Tenedos. In Greece the patriarch still has jurisdiction over the monastic state of Mt. Athos the monastery of St. John the Divine on Patmos, four bishoprics in the Dodecanese headed by the metropolitan of Rhodes and the autonomous church of Crete under the archbishop of Herakleion. Other dioceses dependent on the patriarch of Constantinople include the archbishopric of Thyateira for western Europe, the archbishopric of North and South America and Canada, the archbishopric of Australia and New Zealand and some dioceses in eastern Europe.

Under the patriarch Meletius IV (d. 1923) the Turkish government removed all civil powers from the patriarch. But though his jurisdiction is relatively small, his spiritual authority is of great value in church reunion movements. A historic step in this direction was taken in Jan. 1964 when the ecumenical patriarch Athenagoras and Pope Paul VI met and embraced in Jerusalem. But tension between Greece and Turkey over Cyprus, along with Athenagoras' interfaith interests, which to the Turks appeared political in intent, combined to make the position of the ecumenical patriarchate in Turkey uneasy by the late 1960s. *See also* BYZANTINE EMPIRE; ORTHODOX EASTERN CHURCH.

(H. S. AL.)

**CONSTANTIUS I CHLORUS**, properly AURELIUS VALERIUS CONSTANTIUS (d. A.D. 306), Roman emperor, whose nickname Chlorus means "the Pale." A Dardanian, probably of humble origin (his alleged descent from Claudius II Gothicus is a later fiction), he served in the army as *protector* and tribune and be-

came governor of Dalmatia. On March 1, 293, he was given the title of *Caesar* by the emperor Maximian (q.v.), who adopted him and married him to his daughter Theodora. Constantius already had one son (later the emperor Constantine I) by Helena, whom he now divorced. By Theodora he had three sons, Flavius Dalmatius, Julius Constantius and Hannibalianus, and three daughters, Constantia, Anastasia and Eutropia. As *Caesar* he was assigned the government of Gaul with the task of subduing M. Aurelius Carausius (q.v.), the usurper in Britain. In 293 he captured Carausius' mainland base Gessoriacum (Boulogne), and in 296, after careful preparations, he invaded Britain and conquered Allectus, Carausius' successor. He won a notable victory over the Alamanni in Gaul (298) and restored cities of Britain and Gaul. He was deliberately lax in enforcing Diocletian's edicts against the Christians in 303, only demolishing the churches; there were no martyrdoms in his dominions. When Diocletian and Maximian abdicated on May 1, 305, he became the senior *Augustus*, but died at Eboracum (York) in the summer of 306. (A. H. M. J.)

**CONSTANTIUS II (FLAVIUS JULIUS CONSTANTIUS)** (A.D. 317–361), Roman emperor, third son of Constantine the Great and Fausta, was born in Illyricum on Aug. 7, 317, and was proclaimed *Caesar* on Nov. 8, 324. When his father died on May 22, 337, the troops massacred many of his relatives, allegedly at Constantius' instigation. Constantius then divided the empire with his brothers Constantine II and Constans (q.v.), taking the eastern provinces (Thrace, Macedonia, Greece, Asia and Egypt) for himself. Much of his reign was occupied with repelling Persian attacks on the eastern frontier and with suppressing usurpers. The Persian king Shapur II (q.v.) directed several unsuccessful attacks between 338 and 350 at the important city of Nisibis (Nusaybin) in Mesopotamia, nevertheless inflicting heavy losses on the Romans. Recalled to Europe in 350 by the usurpations of Vetranio, commander of the Danube forces whose troops he won over at Naissus (Nis) in Moesia without fighting, and of Magnentius (q.v.), whom he crushed only after fighting the battle of Mursa (q.v.) in Pannonia (351), Constantius appointed his cousin Gallus *Caesar* (q.v.) to administer the east as *Caesar*, but recalled him and put him to death in 354. In 355 he brought about the murder of Silvanus, a Frank who had usurped the title of emperor at Colonia (Cologne), and in the same year appointed Julian (q.v.), Gallus' half brother, as *Caesar* to govern Gaul. He visited Rome in the spring of 357, and attacked the Sarmatae, Suevi and Quadi on the Danube (357–358). In the meantime Shapur had renewed his attacks on the eastern frontier (359) and captured Amida (Diyarbakir), Singara and Bezabde in Mesopotamia. In 361 Constantius was recalled to the west by the revolt of Julian, but he became ill at Tarsus and died at Mopsucenae in Cilicia on Nov. 3, 361.

Constantius was deeply interested in theological matters: he was an Arianizer and an opponent of the Council of Nicaea (see ARIUS; ARIANISM) and of Athanasius, bishop of Alexandria. Numerous synods and councils were held during his reign, and many bishops were exiled, including Liberius, bishop of Rome. Although Constantius permitted the return of Athanasius to Alexandria in 346, he personally attacked him before the Council of Arles in 353, and the bishop went into hiding in 356. But at the end of the reign none of the questions which divided the supporters of Arius and of Athanasius had been resolved. Constantius opposed paganism, against which he passed several laws.

See A. Pagniol, *L'Empire chrétien*, pp. 325–395 (1947). (E. A. T.)

**CONSTANTIUS III** (d. A.D. 421), Roman emperor in 421, was a native of Naissus (Nis) in Moesia. In 411 as *magister militum* (master of the soldiers) he helped to overthrow Constantine (Flavius Claudius Constantinus; q.v.) at Arles (Arles). He drove the Visigoths from southern Gaul into Spain (415). He forced them to fight the other barbarians already settled there. In 417 he married the emperor's sister Placidia, who bore him the future emperor Valentinian III. Recalling the Visigoths from Spain (418), he settled them in southwestern Gaul. Appointed emperor with the title of *Augustus* on Feb. 8, 421, he died on Sept. 2, 421, at Ravenna. (E. A. T.)

**CONSTELLATION**, in astronomy, the name given to cer-

tain groupings of stars that were imagined—at least by those who named them—to form conspicuous configurations in the sky (from the Lat. *constellatus*, "studded with stars"; *con*, "with," and *stella*, "a star"). Constellations are useful in tracking artificial satellites, and in assisting astronomers and navigators to locate certain stars. There are 88 constellations now universally recognized.

From the earliest times the star groups known as constellations, the smaller groups (parts of constellations) known as asterisms and, also, individual stars have received names connoting some meteorological phenomena, or symbolizing religious or mythological beliefs. At one time it was held that the constellation names and myths were of Greek origin; this view has now been disproved, and an examination of the Hellenic myths associated with the stars and star groups in the light of the records revealed by the deciphering of Euphratean cuneiforms leads to the conclusion that in many, if not all, cases the Greek myth has a Euphratean parallel, and so renders it probable that the Greek constellation system and the cognate legends are primarily of Semitic or even pre-Semitic origin.

The Sumerians and Akkadians, the non-Semitic inhabitants of the Euphrates valley prior to the Babylonians, described the stars collectively as a "heavenly flock"; the sun was the "old sheep"; the seven planets were the "old-sheep stars"; the whole of the stars had certain "shepherds," and *Sibzianna* (which, according to A. H. Sayce and B. Bosanquet, is the modern Arcturus, the brightest star in the northern sky) was the "star of the shepherds of the heavenly herds." The Akkadians bequeathed their system to the Babylonians, and cuneiform tablets and cylinders, boundary stones and Euphratean art generally point to the existence of a well-defined system of star names in their early history. From a detailed study of such records, in their nature of rather speculative value, R. Brown, Jr. (*Primitive Constellations*, 1899) compiled a Euphratean planisphere, which he regarded as the mother of all others. The tablets examined range in date from 3000–500 B.C., and hence the system must be anterior to the earlier date. Of great importance is the *Creation Legend*, a cuneiform compiled from older records during the reign of Assur-bani-pal, in which there occurs a passage interpretable as pointing to the acceptance of 36 constellations; 12 northern, 12 zodiacal and 12 southern. (The zodiac [q.v.] is an imaginary band in the sky, 16° wide, centred on the ecliptic, or the apparent path of the sun.)

The Phoenicians—a race dominated by the spirit of commercial enterprise—appear to have studied the stars more especially with respect to their service to navigators; according to Homer "the stars were sent by Zeus as portents for mariners." But all their truly astronomical writings are lost, and only by a somewhat speculative piecing together of scattered evidence can an estimate of their knowledge be formed. The interrelations of the Phoenicians with the early Hellenes were frequent and far-reaching, and in the Greek presentation of the legends concerning constellations a distinct Phoenician, and in turn Euphratean, element appears. One of the earliest examples of Greek literature extant, the *Theogony* of Hesiod, appears to be a curious blending of Hellenic and Phoenician thought. Although not an astronomical work, several constellation subjects are introduced. In the same author's *Works and Days*, a treatise which is a sort of shepherd's calendar, there are distinct references to the Pleiades, Hyades, Orion, Sirius and Arcturus. It cannot be argued, however, that these were the only stars and constellations named in his time; the omission of other names proves nothing.

The same is true of the Homeric epics wherein the Pleiades, Hyades, Ursa Major, Orion and Boötes are mentioned, and also of the stars and constellations mentioned in Job. Further support is given to the view that, in the main, the constellations were transmitted to the Greeks by the Phoenicians from Euphratean sources in the fact that Thales, the earliest Greek astronomer of any note, was of Phoenician descent. According to Callimachus he taught the Greeks to steer by Ursa Minor instead of Ursa Major; and other astronomical observations are assigned to him. But his writings are lost, as is also the case with those of Phocus

## THE OLD CONSTELLATION FIGURES

### Projected on the Plane of the Ecliptic

the Samian and the history of astronomy by Eudemos of Rhodes, the pupil of Aristotle; hence the paucity of present-day knowledge of Thales' astronomical learning.

From the 6th century B.C. onward, legends concerning the constellation subjects were frequently treated by the historians and poets. Aglaosthenes or Agaosthenes, an early writer, knew Ursa Minor as Cynosura and recorded the translation of Aquila; Epi- menides the Cretan recorded the translation of Capricornus and the star Capella; Pherecydes of Syros recorded the legend of Orion and stated the astronomical fact that when Orion sets Scorpio rises; Aeschylus and Hellanicus of Mytilene narrated the legend of the seven Pleiades. In the 5th century B.C. the Athenian astronomer Euctemon, according to Geminus of Rhodes, compiled a weather calendar in which Aquarius, Aquila, Canis Major, Corona, Cygnus, Delphinus, Lyra, Orion, Pegasus, Sagitta, and the asterisms Hyades and Pleiades are mentioned, always, however, in relation to weather changes. The earliest Greek work which purported to treat the constellations as constellations, of which there is certain knowledge, is the *Phainomena* of Eudoxus of Cnidus. The original is lost, but a versification by Aratus, a poet at the court of Antigonos II Gonatas, king of Macedonia, and a commentary by Hipparchus are extant.

In the work of Aratus 44 constellations are enumerated, viz., 19 northern: Ursa Major, Ursa Minor, Boötes, Draco, Cepheus, Cassiopeia, Andromeda, Perseus, Triangulum, Pegasus, Delphinus, Auriga, Hercules, Lyra, Cygnus, Aquila, Sagitta, Corona and Serpentarius; 13 central or zodiacal: Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricornus, Aquarius, Pisces and the Pleiades; and 12 southern: Orion, Canis, Lepus, Argo, Cetus, Eridanus, Piscis Australis, Ara, Centaurus, Hydra, Crater and Corvus. In this enumeration Serpens is included in Serpentarius and Lupus in Centaurus; these two constellations were separated by Hipparchus and, later, by Ptolemy. On the other hand, Aratus kept the Pleiades distinct from Taurus, but Hipparchus reduced these stars to an asterism. Aratus was no astronomer, while Hipparchus was; and from the fact that the latter adopted, with but trifling exceptions, the constellation system portrayed by Aratus, it may be concluded that the system was already familiar in Greek thought.

Three hundred years after Hipparchus, the Alexandrian astronomer Ptolemy adopted a very similar scheme in his *uranometria*, which appears in the seventh and eighth books of his *Almagest*, the catalogue being styled the "accepted version." The names and orientation of the 48 constellations therein adopted are, with but few exceptions, identical with those used at the present time; and as it cannot be doubted that Ptolemy made only very few modifications in the system of Hipparchus, the names were adopted at least three centuries before the *Almagest* was compiled.

A later innovator of importance was Johann Bayer, a German astronomer, who published a *Uranometria* in 1603 in which 12 constellations, all in the southern hemisphere, were added to Ptolemy's 48, viz., Apis or Musca (bee), Avis Indica (bird of paradise), Chamaeleon, Dorado (swordfish), Grus (crane), Hydrus (water-snake), Indus (Indian), Pavo (peacock), Phoenix, Piscis Volans (flying fish), Tucana and Triangulum Australe. According to W. Lynn (*Observatory*, 1886, p. 255), Bayer adapted this part of his catalogue from the observations of the Dutch navigator Petrus Theodori (or Pieter Dirchsz Keyser; d. 1596).

The *Coelum stellatum Christianum* of Julius Schiller (1627) is noteworthy for the attempt made to replace the names connoting mythological and pagan ideas by the names of apostles, saints, popes, bishops, and other dignitaries and objects of the church. Aries became St. Peter; Taurus, St. Andrew; Andromeda, the Holy Sepulchre; Lyra, the Manger; Canis Major, David; and so on. This innovation (with which the introduction of the 12 apostles into the solar zodiac by the Venerable Bede may be compared) was short-lived. A similar confusion was attempted by E. Weigelius, who sought to introduce a *Coelum heraldicum*, in which the constellations were figured as the arms or insignia of European dynasties, and by symbols of commerce.

In Edmund Halley's southern catalogue (*Catalogus stellarum australium*), published in 1679 and incorporated in John Flam-

steed's *Historia coelestis Britannica* (1725), the following constellations are named: Piscis Australis, Columba Noachi, Argo Navis, Robur Caroli, Ara, Corona Australis, Grus, Phoenix, Pavo, Apus or Avis Indica, Musca Apis, Chamaeleon, Triangulum Australe, Piscis Volans, Dorado or Xiphias, Tucana or Anser Americanus, and Hydrus. Flamsteed's maps also contained Mons Menelai. This list contains nothing new except Robur Caroli, since Columba Noachi (Noah's dove) had been placed in the skies by Jacobus Bartschius in 1624.

In 1690 two posthumous works of Johannes Hevelius (1611-87), the *Firmamentum sobiescianum* and *Prodromus astronomiae*, added several new constellations to the list, viz., Canes Venatici (the greyhounds), Lacerta (the lizard), Leo Minor (little lion), Lynx, Sextans Uraniae, Scutum Sobieskii (the shield of Sobieski), Vulpecula et Anser (fox and goose), Cerberus, Camelopardalis (giraffe) and Monoceros (unicorn); the last two were originally named by Bartschius. In 1679 Augustine Royer introduced the most famous of the constellations of the southern hemisphere, the Crux Australis or Southern Cross.

Nicolas Louis de Lacaille, who made extended observations of the southern stars in 1751 and in the following years, and whose results were embodied in his posthumous *Caelum australe stelliferum* (1763), introduced the following new constellations: Apparatus Sculptoris (sculptor's workshop), Fornax Chemica (chemical furnace), Horologium (clock), Reticulus Rhomboidalis (rhomboidal net), Caela Sculptoris (sculptor's chisels), Equuleus Pictoris (painter's easel), Pyxis Nautica (mariner's compass), Antlia Pneumatica (air pump), Octans (octant), Circinus (compasses), Norma *alias* Quadra Euclidis (square), Telescopium (telescope), Microscopium (microscope) and Mons Mensae (Table mountain).

Attempts have been made to introduce new constellations since that date, but none of these is now accepted. The large Ptolemaic constellation of Argo is, however, subdivided into Vela (sails), Puppis (stern) and Carina (keel).

The delimitation of precise boundaries for the constellations was undertaken by a committee of the International Astronomical union. By 1945 it was possible to assign any star to its proper constellation without ambiguity.

The following list contains the constellations now used. The Ptolemaic constellations are printed in small capitals. Many are the subject of separate articles.

## Northern

ANDROMEDA	CYGNUS	OPHIUCHUS
AQUILA	DELPHINUS	PEGASUS
AURIGA	DRACO	PERSEUS
BOÖTES	EQUULEUS	SAGITTA
Camelopardalis	HERCULES	SERPENS
Canes Venatici	Lacerta	TRIANGULUM
CASSIOPEIA	Leo Minor	URSA MAJOR
CEPHEUS	LYRX	URSA MINOR
Coma Berenices	LYRA	VULPECULA
CORONA BOREALIS		

## Central (Zodiacal)

AQUARIUS	GEMINI	SAGITTARIUS
ARIES	LEO	SCORPIO
CANCER	LIBRA	TAURUS
CAPRICORNUS	PISCES	VIRGO

## Southern

Antlia	Dorado	ORION
Apus	ERIDANUS	Pavo
Ara	Fornax	Phoenix
Caelum	Grus	Pictor
CANIS MAJOR	Horologium	Piscis Austrinus
CANIS MINOR	HYDRA	Puppis
Carina	Hydrus	Pyxis
CENTAURUS	Indus	Reticulum
CETUS	LEPUS	Sculptor
Chamaeleon	LUPUS	Scutum
Circinus	Mensa	Sextans
Columba	Microscopium	Telescopium
CORONA AUSTRINA	Monoceros	Triangulum Australe
CORVUS	Musca	Tucana
CRATER	Norma	Vela
CRUX	Octans	Volans

**CONSTIPATION**, a faulty functioning of the lower bowel resulting in undue retention of fecal material, which usually becomes dried and often hardened. It results from bad habits of personal hygiene, improper diet or disease of the lower bowel. Proper treatment is based upon the recognition and correction of the cause. The habitual use of laxatives and enemas may cause ultimate aggravation of this condition and the production of other disturbances. See **DIGESTION**; **GASTROINTESTINAL TRACT**, **DISEASES OF**. (F. L. A.)

**"CONSTITUTION,"** a United States frigate familiarly known as "Old Ironsides," is the most famous ship in the annals of American history. She was one of the first three frigates built for the United States navy; designed by Joshua Humphreys of Philadelphia, her keel was laid at Hartt's shipyard, Boston, in 1794. Construction was temporarily suspended in 1795, when a tenuous peace was reached with Algiers. Work on the "Constitution" was undertaken again when the need arose to resist the depredations of French privateers then infesting American waters. She was launched in 1797 and, under Capt. Samuel Nicholson, saw her first service in the quasi war with France.

The over-all length of the "Constitution" was 204 ft., breadth of beam 43 ft. 6 in., depth of hold 14 ft. 3 in., displacement 2,200 tons, gun range 1,200 yd. She was originally built of well-seasoned live oak, red cedar and hard pine. Bolts which fastened her timbers and the copper sheathing on the bottom were made by Paul Revere. Rated as a 44-gun frigate, she, however, generally carried more than 50 guns and a crew of over 450. Original cost of the vessel was \$302,718.84, including guns and equipment.

In the successful war against the Tripolitan pirates (1801-05) the "Constitution" was Commodore E. Preble's flagship, and peace was signed aboard her. During the War of 1812 she achieved an enduring place in the American tradition. On one occasion when there was no wind her crew took to small boats and towed her out of reach of the guns of the British fleet. On Aug. 19, 1812, when morale in the United States was at a low ebb, the "Constitution," commanded by Capt. Isaac Hull, won a brilliant victory over the British frigate "Guerriere." Tradition has it that during this engagement the American sailors, on seeing British shot failing to penetrate the staunch oak sides of their ship, dubbed her "Old Ironsides." This frigate duel was followed by numerous other victories hardly less notable, including destruction of H.M.S. "Java" (Dec. 29, 1812), when the "Constitution" was commanded by Capt. William Bainbridge.

The historic old ship was condemned as unseaworthy and it was

recommended that she be broken up in 1828. She was saved, however, when the poem "Old Ironsides" by Oliver Wendell Holmes aroused public sentiment. Through subsequent rebuildings the "Constitution" retained, insofar as possible, her original appearance and characteristics.

After a restoration (1927-31) she called at 90 U.S. ports on both coasts and was visited by more than 4,500,000 people. Returning to Boston in 1934, she has been permanently berthed there and opened to the public. "Old Ironsides" remained on the list of commissioned vessels in the United States navy.

**CONSTITUTIONAL ACT, CANADIAN** (1791). The Constitutional act, otherwise known as the Canada bill, repealed certain parts of the Quebec act (*q.v.*) of 1774 under which the province of Quebec had previously been governed, and provided a new constitution for the two provinces called Lower Canada (the future Quebec) and Upper Canada (the future Ontario) into which the territory was divided. After the American Revolution Loyalist settlers entered Quebec, bringing with them a desire for democratic institutions and for English civil law; the British merchants in the cities of Quebec and Montreal were also clamouring for a legislative assembly. Change was necessary, and the act was passed by the British parliament on June 10, 1791, and proclaimed to take effect on Dec. 26, 1791. The new legislatures, the first in this part of Canada, met in each province in 1792.

The act aimed to reproduce the general principles of the British constitution. There was to be a governor or lieutenant governor in each province representing the crown, advised by an executive council; a legislative council appointed for life by the governor; and an elected legislative assembly. The legislative authority of governor, council and assembly was defined generously as a power to make laws "for the peace, welfare and good government" of the provinces, not repugnant to the act, but bills might be disallowed by the crown in England. To the parliament of Great Britain was reserved the right to control navigation and to regulate the external commerce of the provinces.

Two special provisions of the act showed the fear of egalitarian principles. One provided for the appropriation of crown lands (one-eighth of all future grants) "for the support and maintenance of a Protestant clergy" (see **CLERGY RESERVES**). This portion of the act went into effect, with unhappy consequences to Canadian politics. The other provision sought to establish a landed aristocracy with the hereditary right of being summoned to the legislative council of each province. This feudal idea remained a dead letter, being wholly unsuitable to local conditions.

The wisdom of the policy underlying the Constitutional act has been seriously questioned. D. Creighton, for example, in *The Empire of the St. Lawrence* (1956), observed that Canada was "partitioned by the Treaty of Paris (1763) and repartitioned by the Constitutional Act." Commercial conflict inevitably arose between the two provinces linked by geography and trade routes. Believing that the American Revolution was caused by too much democracy, the English statesmen sought through the act to bolster authority against the popular will. Representative government was, however, introduced, and this led eventually to responsible government. French Canadians found in the legislative assembly of Lower Canada, in which they formed a majority, their first opportunity to express a nascent nationalism.

Bradley, *Lord Dorchester* (1926); *Cambridge History of the British Empire*, vol. vi, *Canada and Newfoundland* (1930). (F. R. S.)

**CONSTITUTIONAL CONVENTION (U.S.)**, an assembly of delegates who met in the Pennsylvania statehouse in Philadelphia during the period May 25-Sept. 17, 1787, and drafted the constitution of the United States, which replaced the Articles of Confederation (*q.v.*). The convention was called as the result of a demand for a stronger central government. By 1787 it

had become extremely doubtful that the Articles of Confederation could be amended to create an effective central regime that would regulate interstate commerce and effectively handle foreign relations. An economic depression, which was at its worst in 1785-86, and a rebellion led by Daniel Shays stimulated action. In the fall of 1786 the Annapolis convention (*q.v.*) issued an invitation to the states to send delegates to Philadelphia "to take into consideration the situation of the United States, to devise such further provisions as shall appear to them necessary to render the constitution of the federal government adequate to the exigencies of the Union. . . ." The congress sent forth a similar request on Feb. 21, 1787, and 74 delegates were chosen by 12 states. Rhode Island failed to appoint deputies. Only 55 men actually took part in the proceedings at Philadelphia; of these, 39 signed the constitution.

The members of the convention were distinguished in ability, education and experience, though hardly more so than those of the second continental congress. They were also men of property, as would be expected. Especially valuable were the contributions of George Washington of Virginia, who played little part in the deliberations but gave the convention dignity and prestige as its presiding officer; James Madison, also of Virginia, statesman-like and prolific in political devices, often called "Father of the Constitution"; James Wilson of Pennsylvania, a strong nationalist; John Rutledge and Charles Cotesworth Pinckney of South Carolina, able and responsible representatives of the deep south; Oliver Ellsworth of Connecticut, a thoughtful and sober man who helped to solve several difficult problems; and Gouverneur Morris of Pennsylvania, who was especially responsible for the clear language in which the constitution was cast.

The convention quickly decided to make a new constitution rather than try to amend the Articles of Confederation. Its basic elements were contained in the Virginia plan, prepared by the Virginia delegation before the opening of the convention and proposed by Edmund Randolph. This plan called for the creation of a powerful central government, including a bicameral congress with the representation of each state based on its population or wealth. Agreement was quickly reached (on May 30) that ample powers must be vested in the central regime, and also (on June 12) that the constitution when finished should be presented for ratification to specially elected conventions in the several states rather than to their legislatures. Later it was stipulated that the constitution should be put in motion when nine such conventions had voted approval. Thus it was arranged that the constitution should have as its basis the solemn will of the people. Accordingly, both the central and state governments came to rest upon them.

The bases for representation in congress proposed in the Virginia plan encountered, however, serious opposition. From the time of the first continental congress each colony-state had possessed (as in the convention itself) one vote; the use of a ratio of numbers or wealth would obviously destroy that system and would give the larger states, especially Massachusetts, Pennsylvania and Virginia, a heavy representation. Bitter protests came from delegates of the smaller states, who were moved not only by state pride but also, and especially, by fear that members of the congress from the large states would combine their votes to dominate it. Massachusetts, Pennsylvania and Virginia, with support from Connecticut, the Carolinas and Georgia, urged the proportional principle for both houses of the congress-to-be. Clinging to their belief that the votes of the large states would be cast in bloc—although Madison correctly declared that voting would be in accordance with sectional, economic and social beliefs rather than according to state size—the small states insisted upon equal representation of the states. They rallied behind William Paterson of New Jersey, who offered the New Jersey plan on June 15. This scheme would have created a one-house legislature in which all states had an equal vote, and would have materially increased the powers of the congress beyond those granted under the Articles of Confederation. Provision was also included for an executive and a judiciary. After some weeks of discussion it became evident that constitutional reform would fail unless concession was made

to the small states. As a result the "Great Compromise," in which the Connecticut delegation played an important role, was arranged by votes taken on July 16 and 23. It called for a bicameral congress with proportional representation in the lower house and equal representation of the states in the upper house, or senate. Thus the convention solved its most difficult problem, and the advocates of a strong central government gained strength, for Paterson and other representatives of small states abandoned their fears of national tyranny.

Further awkward difficulties arose because of conflicting sectional interests, chiefly those of the south and the north. Northern delegates desired representation in the house of representatives in proportion to wealth or free population. Those from Maryland southward insisted that Negro slaves be taken into account either as persons or property. On the other hand, northern spokesmen wished to count the slaves in the apportionment of direct taxes, while southerners were not eager to do so. Ultimately it was agreed that representation should be in accordance with numbers, and that five slaves should be counted as three freemen for both representation and direct taxation. Other delicate problems between north and south arose from divergent opinions regarding export duties, regulation of the oceanic slave trade and navigation acts. The southern delegates desired prohibition of export duties and laws that might give northern merchants a monopoly of southern maritime trade. Men from the deep south also desired a bar against action by congress to destroy the slave trade. New Englanders sought to secure as much of the southern sea-borne traffic as could be gotten for Yankee merchants; and, along with delegates from the upper south, they desired to abolish the oceanic commerce in slaves. After sharp disputes a compromise was finally reached on Aug. 29. By its terms, export taxes were forbidden; the slave trade was exempted from federal interference for 20 years; and passage of navigation acts by simple majority was permitted. The Connecticut delegation, which had been instrumental in arranging the "Great Compromise," also helped materially in the making of this sectional bargain.

Meanwhile the convention reached agreement on various political devices. It enumerated the powers of the central government; provided for a single executive chosen by a complicated system in which the voters, the states and the congress were all to play parts; laid down an outline for a federal judiciary; and adopted a system of checks and balances designed to prevent domination of the federal government by the president, the congress or the judiciary. The delegates did not provide specifically for judicial review of legislation but they apparently expected it to take place. They declared the constitution to be "the supreme Law of the land." They also failed to insert a full federal bill of rights, in part at least because they thought one unnecessary.

Although several delegates, including George Mason and Edmund Randolph of Virginia and Elbridge Gerry of Massachusetts, refused to approve the constitution, it was referred to the states by the old congress, and was endorsed by 11 state conventions by July 1788. North Carolina and Rhode Island withheld their sanction until after the new federal government was put in motion in the spring of 1789.

There has been much dispute among scholars concerning the achievement, the intentions and the motivations of the men who made the constitution and secured its adoption. In the latter part of the 19th century and the early years of the 20th both popular and scholarly opinion held that the constitution was an almost perfect document made by wise and altruistic men. It was generally believed that its adoption rescued the United States from economic distress and near anarchy during the years following the Revolutionary War. But in 1913 Charles A. Beard in *An Economic Interpretation of the Constitution* stimulated more sophisticated analysis. Beard contended that the making and the ratification of the document were the work of men who were merchants, lawyers, manufacturers and capitalists, dominated by interests in personal property, especially national certificates of indebtedness. He also offered data tending to indicate that the constitution was opposed by a majority of the voters in several states and that it probably was not favoured by a majority of the

American people; hence that its adoption was "undemocratic." Other writers following in his wake claimed that the adoption was the equivalent of the Thermidorian reaction in the French Revolution.

It should be observed that the process of adoption was as "democratic" as the ones employed in the ratification of state constitutions at that time, and that the provisions of the document were approximately as "democratic" as those of the average contemporary state constitution. There was, accordingly, no remarkable conservative reaction in 1787-88. Moreover, scholars have properly pointed out that possession or nonpossession of certificates of indebtedness could not of themselves have determined attitudes toward the constitution. Indeed, as Robert E. Brown and Forrest McDonald have asserted in critiques of Beard's work, conclusive evidence is lacking that economic status in general dictated allegiance or opposition to the constitution. In the debates over the influence exerted by the economic situations of persons and classes, arguments in behalf of the constitution for the general good have received insufficient attention. Yet it is clear enough that it offered promise of a respectable and dignified central government in which the Americans could take pride, of economic benefits to the American people as a whole and of solid improvements in the management of foreign affairs, defense and Indian affairs. ## CONSTITUTION AND CONSTITUTIONAL LAW.

In its wider sense the term "constitution" means the whole scheme whereby a country is governed; and this includes much else besides law. The constitutional lawyer must constantly keep glancing backward into constitutional history; he must also keep his eye on current political practice and the day-to-day working of political institutions. In its narrower sense "constitution" means the leading legal rules, usually collected into some document which comes to be almost venerated as "The Constitution." But no country's constitution can ever be compressed within the compass of one document and even where the attempt has been made it is necessary to consider the extralegal rules, customs and conventions that grow up around the formal document. It is essential to note in this regard that constitutional government is limited government; it requires that public authority be exercised according to law. (For the relationships of the U.S. constitution to constitutional law, see *United States*, below.)

### CONSTITUTIONS IN GENERAL

It is almost impossible to give a satisfactory or comprehensive definition of constitutional law in the United Kingdom, and it is discussed more fully below (see *The English Constitution*). There are good historical and political reasons for this difficulty of definition, and today it is perhaps permissible to say, quite baldly, that constitutional law is the law relating to the government of the country, to the state and its various organs and their relations among themselves and with the ordinary citizen. There is in English law no real distinction between public and private law just as, in the middle ages, there was no distinction between property and government; both then were different aspects of the same thing; today public and private law are often inextricably mingled. But the main essentials of constitutional law are clear: they include all the rules relating to the crown and its powers or prerogatives; the composition, functions and powers of parliament; the executive, by which is meant all the various organs of central government that are collectively known as "Whitehall"; the duties and powers of the courts; and, not least, the rights and duties of the citizens: "the liberty of the subject" in a time-honoured phrase.

**Written Constitutions.**—In most western countries the constitution, using the term in the narrower sense, is a scheme of government that has been deliberately adopted by the people; examples are the constitution of the United States, drawn up in 1787 and ratified in 1789 and still in essentials unchanged; the constitution of the Weimar republic or that of the Federal Republic of Germany brought into force in 1949; the constitutions that France has had since the Revolution. These are "written" constitutions in the sense that there is some document or series of documents setting out the fundamental principles and chief legal rules, and to this the student can point and say "this is the constitution." The constitution in these countries is the basis of public law; it is usually enacted or adopted with special formalities; special processes are devised for its amendment (and sometimes safeguards are inserted to ensure that certain provisions are unalterable); and constitutional law comes to enjoy a special pre-eminence. In this type of constitution the courts have a special function: if some act of the legislature exceeds the powers conferred by the constitution, the courts must declare it to be unconstitutional and so null and void. The supreme court of the United States, for example, has again and again declared whole acts or clauses of particular acts to be *ultra vires* ("outside the powers") or to contradict some fundamental rule of the U.S. constitution. Thus in countries with a written constitution the judges have the very important task of passing on the validity of legislation, and for this reason appointments to the bench are sometimes matters of more than purely legal interest. Pres. Franklin D. Roosevelt inherited a supreme court that was not sympathetic to his views; all his nominations were from those who favoured his New Deal, and there were at times complaints of packing the bench. Since World War II the decisions of the constitutional court in the Federal Republic of Germany have been issues of first-class political importance.

Switzerland, France, Italy and the U.S.S.R. have constitutions of this type; so have the self-governing members of the Commonwealth of Nations, though in none is the emphasis on the judicial review of legislation and governmental acts so great as in the United States.

Written constitutions are sometimes also described as "rigid" meaning that they can be altered only in special ways, usually designed to guard against hasty action by majorities. Thus in the United States to propose amendments requires two-thirds majorities of both houses of congress, or a convention called on application of two-thirds of the state legislatures, and any amendment made is not effective until ratified by three-fourths of the states of the union; sometimes the process of ratification takes years. In France an amendment of the constitution must be approved by both assemblies and then by a referendum or, if the president so decides, the proposal may be submitted to a joint session of both houses sitting as congress, in which event the amendment is accepted only if it obtains a majority of three-fifths of the votes cast. In Belgium and in South Africa there must be a prescribed majority; in Switzerland and Australia a referendum is necessary. Sometimes, too, certain religious or social ideas are written into the constitution as "fundamental rights," and provision is made to ensure that they, as the religious and social basis of the state, are not altered or abandoned. This has happened in countries as divergent as the Republic of Ireland, Israel, India and Pakistan. Finally, it must be noted that there is a further distinction between unitary and federal states. In a unitary state, power is ultimately, concentrated in one centralized government. In a federation each of the constituent states joins with its fellows to form a new state, the federal government, but the member states retain their own organizations and individuality. The instrument creating the federation (the constitution) sets out the powers and duties of the federation and those of the member states and often contains an elaborate system of checks and balances to ensure that the states do not trespass on the federation nor it on them. The demarcation of respective spheres gives rise to some of the nicest questions of federal law, and the task of the supreme court in such a situation can be very delicate. The United States, Canada, Australia, Switzerland and, to some extent, the Federal Re-

public of Germany are examples of federation.

The "unwritten" (in the sense of not being contained in a formally enacted document) nature of the British constitution contrasts largely with every other country. In France the constitution adopted in 1946 was superseded on Oct. 5, 1958, by one containing 92 articles grouped under 15 titles. Art. i establishes the republic and the overseas French territories as a community. Art. ii reaffirms the traditional notions: France is "an indivisible, secular, democratic and social republic"; the Tricolour is the national emblem and the *Marseillaise* is the national anthem; its motto is "liberty, equality, fraternity"; its principle is government of the people, for the people, by the people. Art. v to xix define the powers and functions of the president; other articles create a parliament of two houses (the national assembly elected by universal suffrage, a senate elected indirectly). There is also provision for a constitutional council, the judicial authority, an economic and social council and the institutions of the overseas territories in the community. The general effect of the new constitution was the strengthening of the office of president and the rural, traditional elements in France and the weakening of parliament and the "popular" elements. Similarly, the constitution of the Federal Republic of Germany, promulgated on May 23, 1949, contains 146 articles. The first 19, dealing with fundamentals of state authority, cover the rights of the citizen, the economic order, family and motherhood, education and religion. The remainder deal briefly with relations between the federation and the *Länder*; with legislation; with the powers of the executive, the president and the courts. The final article provides for a constitution to be adopted later "by a free decision of the German people." India has gone to the other extreme, and its constitution runs to about 250 printed pages.

In every other European country and in the commonwealth the pattern is the same: a constitutional document, setting up a legislature, defining its composition and powers; constituting an executive and providing for the exercise of executive powers; creating courts and regulating the judicial function; establishing and often guaranteeing the rights of the individual citizen; and in some cases dealing with local government as well. In federal and quasi-federal countries the picture is more complicated as it is necessary to provide for the division of authority between the federation and its members and for deciding the disputes to which any such distribution must give rise. Usually some topics are assigned exclusively to the federation; others are reserved exclusively to the constituent states or provinces; and there is often a third list of subjects over which both federal and state authorities have concurrent jurisdiction. In such cases it is also necessary to decide which of the concurrent authorities is to prevail if there is a conflict. A method of constitutional amendment is also generally provided.

These countries, then, have constitutions that consist primarily of rules of law. But in addition many are prefaced by a preamble which sets out in general terms the fundamental moral and political principles of the state. This preamble often reads more like a manifesto than a legal document and the principles it sets forth are often incapable of direct legal enforcement. Thus the French constitution begins "... the French people solemnly proclaim their attachment to the Rights of Man and to the principles of national sovereignty as defined by the declaration of 1789, confirmed and completed by the preamble to the constitution of 1946" (which had included the words "every human being, without distinction of race, religion, or belief, possesses inalienable and sacred rights," the substance of which now appears in art. ii). The constitution of the Federal Republic of Germany achieves much the same result; art. i proclaims that the dignity of man is inviolable; art. iii that men and women have equal rights; art. v that art and science research and teaching are free; and so on. The preamble to the constitution of India proclaims justice, liberty, equality and fraternity as its objects. Modern constitutions generally proclaim the sovereignty of the people; some, as in Ireland, South Africa and Switzerland, invoke the sanction of God.

In general a written constitution sets out the principal legal rules

for the distribution and exercise of state authority and provides a means of enforcing them. Sometimes, almost by accident, quite minor rules have been included. Sometimes, under the guise of legal rules, fundamental concepts are set out in such general terms that enforcement is not really possible. Thus the constitution of India sets out "Directive Principles of State Policy," which, although fundamental in the governance of the country, are recognized not to be legally enforceable. Pakistan has provided for certain Islamic principles, and the Republic of Ireland has written into its constitution Catholic social ideals. Ireland, Norway and Denmark have inserted guarantees for the right of private property in their constitutions.

Certain similarities may be noticed. Most constitutions have a bicameral legislature, though the powers of the two houses are not always identical. One house, usually the largest, is elected by universal suffrage; the other is often indirectly elected, as in France, or nominated, as in Canada. In federations the second chamber, as in Canada and Australia, is designed to preserve the equality of the member states and thus gives equal representation to each irrespective of its size, wealth or population; while the elective chamber is generally chosen on a population basis, so that regard can be had to the relative size and numbers of each state. In some there is provision for referendum; i.e., for a proposed law to be directly submitted to the people; Australia, Ireland, Denmark and Switzerland all employ some form of referendum. Sometimes a constitutional amendment is binding only if ratified by a certain number of the member states: one-half of the member states in India; three-fourths in the United States.

In form a written constitution derives its authority from God, the people or a constituent authority. In those countries where constitutions are derived from the United Kingdom the authority of the British parliament as lawmaker for the empire (as it was in the days when the constitutions of the older commonwealth countries were formulated) is sufficient; the British North America acts, the Commonwealth of Australia act, 1900, and the South Africa act, 1909, were all enacted at Westminster. But what of the authority of a constitution once it has been enacted? In the United Kingdom this question does not really arise. Constitutional law is only one branch of the common law; it enjoys no special sanctity; it can be made, altered or repealed in just the same way as any other law. The constitution is the law, but parliament, the omniscient legislature, can make or unmake it. A parliament or its equivalent is, however, only one of a number of state institutions, and generally the constitution precedes the institutions it creates and, just as it precedes them, so it regulates them. In this view the constitution limits the powers of all the constituent organs, the legislative no less than the others. It is, therefore, fundamental, superior, paramount law; its authority and sanction are higher than those of ordinary laws, which are, on this theory, derived from it; hence the special modes of constitutional amendment when the legislature can amend ordinary laws by a simple majority.

It is this view that gives constitutional law a superior, moral, binding force, either because it is the will of the people or the product of a supreme lawmaking authority, such as a constituent assembly; and it is because of this view that once a constitution is accepted it receives the support, in society, of a whole series of forces working against change and in favour of existing institutions. It leads directly to the theory that "constitutionalism" is something sacred, if not an end in itself.

**The Citizen and the State.**—The citizen in a democratic country enjoys freedom of speech, the right to say or publish what he pleases, freedom from arbitrary arrest, freedom to practise his religion and freedom of association; i.e., to form political parties, clubs, trade unions or any other organization he wishes. In most countries these rights are written into the constitution by being specifically enumerated and enacted as part of the constitutional document itself. In the United Kingdom these freedoms exist as fully and as extensively as anywhere else; but there are no constitutional guarantees of liberty, no safeguards in any enacted constitution. These rights are derived simply from the ordinary law of the land. For example, a discussion of freedom of speech

would involve questions of criminal law (sedition, obscenity and blasphemy) and of private law (libel and slander); the extent to which freedom from arrest is enjoyed can be found only by considering, in the criminal law, the instances in which a man can be apprehended and, in the civil law, the remedies available to one who is wrongfully arrested (damages for false imprisonment or malicious prosecution; habeas corpus; the use of reasonable force in self-defense). These traditional liberties have had to be fought for but today are taken very much for granted; the very fact that there is so little enacted law relating to them is evidence of public assurance of their safety and security. Carried to its logical conclusion this absence of precise definition means, for example, that technically no citizen is safe in criticizing another without first studying the law of defamation carefully or in attacking the government without first informing himself as to the law of sedition. But in practice there is a wide toleration of all utterances on matters of public concern, and the stricter view that is taken of utterances or writings relating to the reputation of private individuals generally meets with public approval.

Freedom of property, however, stands on a very different footing. The crown (on behalf of the central government), every local government authority and most public boards (such as those that run the nationalized industries) have powers to acquire the land of a private individual if it is required for a public purpose (such as building schools or roads or providing a police station or hospital). The citizen is always entitled to compensation; there is a form of public inquiry before the order authorizing the acquisition of his land is made; but there has been great disquiet over the arbitrary way in which these powers have on occasion appeared to be exercised.

**Administrative Law.**—The exercise of powers such as those just described leads naturally into the field of administrative law, by which is meant the law relating to public administration, a vast subject of which it is proposed to mention only two aspects: administrative tribunals and delegated legislation. This field has developed rapidly since World War I and is still developing at a great rate. It is a topic that causes anxiety wherever the traditional western views on constitutional propriety have prevailed and nowhere more than in the United Kingdom. The growing complexity of the state's functions, particularly in matters of economic regulation, currency control, social welfare, education and health, has led to a great increase in the powers of the executive to control business, commerce, manufacture and the private life of the citizen at many points. To carry out these functions almost every government department has wide compulsory powers; powers to order, direct, regulate, license, forbid, acquire property. The carrying out of these schemes invokes a mass of detailed rules and regulations; the typical statute is not suited to minutiae; parliament has neither the time nor the knowledge to discuss these problems adequately. Hence the modern practice is for a statute to lay down general principles and leave the details to be filled in by ministerial order; *i.e.*, by orders made by the government department concerned. These orders, of which until 1949 over 2,000 were made annually (since then the annual output has shown some decline), are known as "delegated legislation." They are legislative because they make new law or change existing law; they are delegated because parliament has delegated the power to legislate to a subordinate authority.

Thus a modern ministry is invested with: (1) a power to compel; (2) a power to decide disputes; (3) a power to legislate. This cuts across the traditional theory of the separation of powers in that it confers legislative and judicial authority on the executive. This field, as already pointed out, raises the most difficult constitutional issues. The older view is that the traditional liberties are in danger; the modern view is that without such power the welfare state could not operate and that parliament, which conferred them, can also control them. Perhaps the most urgent issue is to devise some efficient control by parliament over delegated legislation and by the courts (or by some other independent authority) over the exercise of administrative powers.

Delegated legislation in England is subject to safeguards to ensure publicity and availability to the public by prompt publica-

tion under rules enacted by the Statutory Instruments act, 1946. Each house of parliament also has a select committee to scrutinize rules made under delegated powers and to report any unusual or improper exercise of the power. But the complexity of the rules and the pressure on parliamentary time make these safeguards less effective than it was hoped that they would be.

The Franks committee on administrative tribunals and inquiries (1957) examined the whole field of administrative law, and many of its recommendations were carried out administratively and as a result of the Tribunals and Enquiries act, 1958. A common procedure for inquiries has been evolved; the objector is enabled to have notice of the public authority's proposals; the inspector's report is to be published and also the minister's reasons for not accepting it, if in fact its recommendations are rejected; the supervisory powers of the high court have been extended; and a standing council on tribunals (with another for Scotland) makes an annual review and reports on the constitution and working of tribunals. These measures have gone a long way toward meeting the disquiet felt by critics of the system.

In the United States similar problems have arisen, and American experience has prompted some of the English criticism and the expedients adopted to meet it. In the United States the "due process" rule is a far more potent curb on administrative actions than any rule or doctrines in England, though the idea of "natural justice" has had, on occasion, not dissimilar results. Delegated legislation in the United States is subject to greater safeguards, and the process by which it is made is more fully regulated. This indeed, is inevitable under a written constitution. The technique of the "public hearing" has been more fully developed, and a complicated adjudicatory procedure, with guarantees of the right to be heard in public and minimum standards for proof and procedure for administrative agencies and commissions, has been evolved, much of it based on the Federal Administrative Procedure act, 1946. Judicial review and access to the courts are ensured by carefully drawn safeguards, and these forms of remedy are probably better provided for than in England.

Notwithstanding these elaborate codes, criticism of the administrative system continues in both countries. Much thinking and writing have been done on both sides of the Atlantic and much controversy evoked. If a satisfactory solution was not in sight by the 1960s, developments then in progress were a great advance, and it was not doubted that parliament, congress and the common law in the United States and in England, all hardy growths, would ultimately find a means of reconciling the need to control persons and property in the public interest with the right of the individual "not to be pushed around." (See also ADMINISTRATIVE LAW; REGULATORY AGENCIES.)

**Constitutionalism.**—This means that public authority is to be exercised according to law; that state and civic institutions, executive and legislative powers, have their source in a constitution, which is to be obeyed and not departed from at the whim of the government of the day; in short, a government of law and not of men. To a greater or lesser degree the idea implicit in the word is respected in every country with a written constitution and in none more than the United Kingdom with its unwritten constitution. It is latent in Lord Chesterfield's oft-quoted dictum in the 18th century: "England is the only Monarchy in the world that can properly be said to have a constitution." It is this idea, and the esteem in which it is held, that will ensure that administrative law and delegated legislation adapt themselves to the parliamentary sovereignty and the rule of law.

### THE ENGLISH CONSTITUTION

In England there is no one document or fundamental body of law that can be described as a "constitution" in the sense that has been discussed above. The absence of any such document or of any distinction between public and private law has led to the suggestion (perhaps first made by A. C. de Tocqueville) that there is in England no constitution. Certainly the English constitution has no existence apart from the ordinary law; it is indeed part of that very law. Magna Carta, the Petition of Right act, the Habeas Corpus act, the Bill of Rights and the Act of Settlement

are the leading enactments, but they are in no sense a constitutional code, and without a host of judicial decisions, scores of other statutes of much less importance and a mass of custom and convention, these statutes would be unworkable. The sources of English constitutional law are diffuse—statutes, judicial precedent, textbooks, lawbooks, the writings of historians and political theorists, the biographies and autobiographies of statesmen, the columns of every serious newspaper, the volumes of *Hansard*, the minutiae of every type of government record and publication. This is what is meant by saying the English constitution is "unwritten"; it is not formally enacted; its rules have to be sought out in a dozen fields, not in any one code. Similarly, it is flexible, and here the contrast is with a rigid constitution. There are no special safeguards for constitutional rules; constitutional law can be changed, amended or abolished just like any rule of private law; there is no field in which parliament is forbidden to legislate; there are no fundamental or unalterable "norms" and no procedures to prescribe delay or extra processes for constitutional change. Thus an act passed through all its stages in both houses and received the royal assent all in one day (May 22, 1940); it is true that the nation was gravely menaced at the time, but the measure, the Emergency Powers (Defense) act, 1940, required persons to place "themselves, their services and their property at the disposal of His Majesty." Earlier, in Dec. 1936, the Abdication act had the same rapid passage into law; it is doubtful if the institutions of any written constitution would permit of such far-reaching changes with so little formality and fuss. Moreover, since parliament is fully sovereign, it is not open to the courts to declare that an act of parliament is unconstitutional or void; all the courts can do is to interpret acts and enforce them (though it must be added that the process of interpretation can produce results that have on occasion largely stultified the purpose of the act). In *Lee v. Bude and Torrington Junction Railway Co.* (1871), a great judge said: "I would observe, as to these Acts of Parliaments, that they are the law of the land, and we do not sit here as a court of appeal from Parliament." The function of the courts is much more limited than in a country where judicial review is a recognized check on legislative activity.

So much, then, for the unwritten, flexible English constitution; why it developed in this way can be answered only by dipping into constitutional history. In the middle ages a strong centralized monarchy slowly and painfully emerged from the remains of the feudal kingdom; it was not perhaps until the time of Henry VII that the monarchy really came into its own. But at the same time the kings had called for and fostered the institution now known as parliament—a development from the feudal great council reinforced by "popular" elements from the counties and boroughs—and the institution in its time was to challenge the crown. By the end of the Stuart period the victory of parliament was assured; the crown lost its more objectionable powers; parliament established its legislative and financial supremacy; and the houses of Orange and Hanover were called in to provide rulers who would accept the new situation. A logical people would have formally transferred the powers of the crown to parliament or to some new organ. In fact the crown was left with most of its prerogatives and was expected to carry on the routine of government; yet for money and legislation, without which it could not govern, it depended on parliament. To fill the gap between the legal "sovereignty" of the crown and the political fact of parliament's supremacy, a new institution, the cabinet (*q.v.*), was called into being. The cabinet consists of the leading members of the party that has a majority in the house of commons and thus can command the support of parliament for its policies. At first, attempts were made to control cabinets in the royal interest but soon the convention of ministerial responsibility grew; this means, in brief, that the sovereign never exercises any of his or her powers without the advice of a minister nor refuses to exercise these powers when a minister advises him to do so. This is well recognized, and thus responsibility for any royal act is always laid at the door of the minister who advised it, not that of the sovereign in whose name it was done. With the doctrine of ministerial responsibility there also developed the parallel doctrine of collective

responsibility of the cabinet: it speaks with one voice; each member is fully responsible for the acts of all the others; any member who disagrees with the majority's policy must hold his peace or resign.

In the 19th century the franchise was gradually extended until, in 1928, every man and woman was potentially entitled to a vote at 21. At the same time each of the great political parties acquired an organization, a discipline and a policy that enabled its leaders to count on the unquestioned support of their followers in the house of commons. So long as the cabinet can command its own supporters it enjoys a virtual monopoly of legislative and executive powers, since the royal prerogatives and the parliamentary timetable are at its disposal. It is for this reason that the large legal powers of the crown are tolerable in a political democracy; they are in effect the sinews of party government; and it was this that A. V. Dicey had in mind when he said that the prerogatives of the crown had become the privileges of the people. Since, too, parliament has by and large controlled the crown for 150 years and, more recently, the party has controlled parliament, there has never been any urge to impose limitations or restrictions on the crown's powers. Naturally enough, parliament has not felt moved to put fetters on itself. Hence the absence of the limitation on these legally wide and discretionary powers; public opinion, party feeling, the ballot box are the real safeguards in modern Britain.

It remains to describe in outline the leading institutions of the British constitution and to show their relations one to another.

**The Crown.**—Title to the crown is now statutory; parliament has changed the succession from time to time, and the British royal house derives its title from the Act of Settlement which limited the crown to the descendants of Sophia, electress of Hanover, being Protestants. Coronation is a religious and civic ceremony but has no legal significance today. The new sovereign's reign begins from the death of his predecessor; in the words of the law "the king never dies." Similarly the king at law was never an infant, and where there was a minority *ad hoc* arrangements were made. Nowadays the minority, incapacity or absence from the country of the sovereign is provided for by the Regency acts of 1937–53, which allow for the appointment of a regent in the case of minority (which ends at 18) or of counselors of state if the sovereign is ill or abroad. The regent or the counselors exercise, with important limitations, the power of the crown.

In theory and in law the powers of the crown—called the prerogatives—are very wide. Walter Bagehot, writing in 1860, startled his contemporaries by enumerating the things that the queen could legally do of her own motion and without anybody's consent. In fact the prerogatives are the sinews of government and have been allowed to survive, substantially undiminished, because the doctrine of ministerial responsibility has made them available to the government of the day, and thus it was convenient, as well as acceptable to a conservatively minded people, to leave them where they were. (*See PREROGATIVE.*)

Socially and politically, however, the more important functions of the monarchy are those that have a popular appeal. The sovereign, and other members of the royal family, frequently pay visits, open hospitals, attend sporting and other entertainments and inaugurate or patronize with their presence a host of national, municipal and local activities. The royal family is the focus of good will in the community; every religious, social or charitable movement can count on its support. In no sphere is this more marked than in relations with countries of the commonwealth. Since the Statute of Westminster, 1931, the legal links between the United Kingdom and the self-governing members of the commonwealth have been practically nonexistent. Each self-governing member is independent of the United Kingdom both internally and internationally; yet all are united by a common allegiance to the crown, and it is the crown as a symbol of a common allegiance that binds the countries of the commonwealth together more closely and more effectively than any formal or legal ties. When India and Pakistan adopted republican forms of constitution, they continued to recognize the queen as head of the commonwealth, membership of which they retained.

The crown is the formal legal institution; in it and through it all the prerogatives are exercised; it is an essential part of parliament; it is the executive ("her majesty's ministers," "her majesty's civil service," "her majesty's prisons," "the Royal Navy" are not empty phrases but correctly describe the legal status of the bodies or institutions to which they refer); the courts are the sovereign's courts, and justice is administered in her name by her judges. Yet the monarchy is something real and personal to every citizen, and the activities of the royal family are followed with interest, affection and often enthusiasm throughout the English-speaking world and beyond.

**The Legislature.**—The legislature or, more properly, the king or queen in parliament consists of the sovereign, the house of lords and the house of commons. The sovereign's part is today largely formal and normally undertaken wholly on ministerial advice. The royal proclamation dissolves one parliament and summons another. The sovereign can, and often does, open the new session in person by reading the royal speech. This sets out the government's proposals and policy, but it is in the first person and reads as if the proposals and policies were the sovereign's. The royal assent is necessary to every bill before it becomes a statute and so achieves the force of law. This is usually given by commissioners specially appointed by the queen to assent in her name, but there is no reason why a sovereign should not assent in person, and George VI did give his assent personally to various Canadian statutes on the royal visit to Canada in 1939. (For the composition, general functions and privileges of the house of lords and of the house of commons, see PARLIAMENT; for the process of legislation, see GREAT BRITAIN AND NORTHERN IRELAND, UNITED KINGDOM OF: *Constitution and Government*.)

Finally, in addition to legislation and finance, the commons, and to a lesser extent, the lords, are important because they provide means whereby public opinion can be focused and pressure brought to bear on the government. A debate in either house, a motion on the adjournment, a series of questions can have important results in modifying or even changing government policy. Members of parliament constantly visit their constituencies; their ears are to the ground; they are the targets of all sorts of "pressure groups" and organized interests. By these means they can and do reflect the state of feeling and opinion in the country, and they, in their turn, get this across to the government. A seemingly inconsequential debate, in which member after member said the same thing, or a question, ostensibly repeated in slightly different forms time and again, are far more important than the casual observer would suppose. It is in these ways that public opinion makes itself felt and the workings of government are kept, in some sort, in harmony with democratic processes.

**The Executive.**—The king or queen in council is the head of the executive. Some functions of the crown can be exercised orally; others require a formal legal document, such as an order in council, letters patent or the fixation of the great seal. These formal matters are considered in the privy council (*q.v.*), a body of great antiquity and descended, in some sense, from the witan of the Saxon kings. Historically it has always been the duty of the crown to seek counsel and of the great in church and state to tender it. Under the Normans the king's council consisted of the archbishops, bishops, abbots, earls and barons and also a number of officials, clerks and royal officers, all of whom owed their place to the king and who, following him on the various royal progresses through his possessions, constituted his household. Soon a struggle developed between the feudal element (the baronage) and the "familial" element or officials. While the claim of the baronage to attend the council was never formally abandoned (and today the house of lords has aspects that show its origin as a council), the kings soon established their right to summon whomever they pleased to the council, which became a small body of great officials and royal favourites in constant attendance on the king. When English terms came into use, this body became known as the privy (or private) council to distinguish it from the great council (now the house of lords), which met in public. It remains, legally, the source of all formal royal acts; but since the evolution of the cabinet, its political functions have declined, and

it is no longer an advisory body. Policy decisions are taken in the cabinet; the formal steps necessary to carry such decisions into effect are taken in the privy council.

Today membership is regarded as a great honour and is conferred on statesmen (from the commonwealth as well as from the United Kingdom) and on judges and other high officials. The body consists of between 200 and 300 members, but in practice the full council never meets, and only the two or three members particularly concerned with the business to be transacted attend. The sovereign is always present and the lord president of the council; and if, for example, foreign and colonial affairs are in issue, the foreign and colonial secretaries will also be there. All cabinet ministers are sworn members of the privy council.

From the council all the great historic offices of state are descended. The office of lord high chancellor, the treasury and the admiralty go back in an unbroken line to the middle ages. The secretaryship of state and the lord president of the council date from the Tudor period; they were the instruments through which the Tudor monarchs modernized the medieval system of government. The board of trade and the ministries of education and agriculture were originally committees of the privy council that grew in importance and became separate departments. Most of the other departments, now called ministries, are of more recent origin and depend for their creation and function on a statute. For an account of the central government departments, see GOVERNMENT DEPARTMENTS. For the list of officials who staff them, see CIVIL SERVICE. For the power and forms of governmental authority, see PRIVY COUNCIL; PREROGATIVE.

The cabinet, already briefly mentioned, is the mainspring of all governmental activity and is one of the great contributions of Great Britain to political institutions. It is presided over by the prime minister (*q.v.*), who is the head of the administration.

**The Judiciary.**—Constitutionally the importance of the judiciary lies in its independence so that it can act as an impartial mediator between the citizen and the state. Judges of the high court enjoy office during good behaviour and are only dismissible on an address voted by both houses of parliament; no judge has ever been removed under this procedure. Their salaries are paid out of the Consolidated fund and are not subject to ordinary executive control. They cannot be criticized in parliament unless a member is prepared to go to the length of putting down a substantive motion. They enjoy a wide immunity from actions in respect of words spoken by them or things done on their orders in the course of their duties. Similar, though not quite so extensive, immunities are enjoyed by the judges of the lesser courts.

All this has created a tradition and a climate of opinion in which the independence of the judges is regarded as almost a fundamental dogma. Any attempt to interfere with any judicial process or to hinder a judge in the execution of his duties would cause a tremendous outburst of popular indignation. Perhaps the most important aspect of this tradition today is that, taken by British judges to the overseas possessions of the crown, it has helped to implant high standards and to impart a feeling of confidence and impartiality in lands where British justice is an alien importation.

## UNITED STATES

**Origins.**—The constitution of the United States was written in Philadelphia during the summer of 1787 by a convention of 55 delegates and, after ratification by the necessary number of states, went into effect on March 4, 1789. (For the text see UNITED STATES (OF AMERICA): *Administration and Social Conditions*.) It was a product of historical experience. For one thing, its authors drew heavily upon the constitutions which the various individual states had adopted in the years immediately following the Declaration of Independence (q.v.). These important documents summarized in constitutional language the prevailing political philosophy of the age, and particularly the idea that governmental power must be limited if the liberty of the citizen is to be secure. The separation of the legislative, executive and judicial branches of the government (see *The Separation of Powers*, below), the checking and balancing of each against the others and the spelling out of guarantees of individual liberty in bills of rights were all designed to find a balance between authority and liberty. This remains the central purpose of American constitutional law.

Furthermore, the authors of the United States constitution were heavily influenced by the experience of the country under its first written national constitution, the Articles of Confederation (q.v.). Dating from 1781, this short-lived document attempted to retain intact as much of the independence and sovereignty of the states as possible and at the same time establish a central government to carry out functions of national importance which the states could not handle individually. Perhaps the greatest lesson of the period 1781-87 was that this could not be done, for it was clear that under this confederate arrangement the national government lacked many essential powers: it had no independent taxing power and was obliged to beg from the states by a system known as requisitions; it could not regulate interstate and foreign commerce and was thus unable to safeguard vital national interests; it could enact laws on a limited number of subjects but had no powers of direct enforcement, thus being required to rely upon the state governments. Being weak, the national government was ineffective in the important field of foreign affairs. At home it was unable to restrain various types of economic radicalism then rampant in many states. In addition, the national government lacked adequate institutions under the Articles of Confederation, since about all these created was a congress. There was no chief executive and no national judiciary. Finally, since the Articles of Confederation could be amended only by the unanimous vote of all the states, it quickly became apparent that the document was in fact unchangeable. This soon spelled its doom and invited the writing of an altogether new document.

In many ways the constitution was a product of compromise on the part of the hardheaded realists who wrote it. The heated quarrel over representation in the new congress, which brought the convention to the brink of failure, was compromised by giving the states equal voting power in the senate to satisfy the demands of the small states and representation in the house of representatives according to population to satisfy the large states. The dispute over the counting of slaves in computing population was resolved by the three-fifths clause (art. i, sec. 2, now obsolete), and that over the commerce power by the prohibition of export taxes. While the compromises of the convention are generally stressed, the area of agreement upon some of the central and immediate issues of the times was far more significant than the area of disagreement. The necessity of a strong national government endowed with adequate powers and institutions was recognized, and it was agreed that the rights of private property must be protected from the inroads of agrarian radicalism: hence the prohibition of state-issued paper money and the protection of contracts against impairment by local legislation (i, 10).

**The Constitution as a Document.**—Under the United States constitution, the oldest written national constitution in operation in the world, the country grew and prospered and remained united, and the basic rights of man proved to be secure, in spite of all the profound changes, economic, social, cultural and political, which occurred after 1789. Many factors explain the continuing vitality of this 18th-century document. In contrast with some prolix state constitutions which are loaded down with provisions designed to appease temporary sentiments or interests, it is a brief and well-written document of about 7,000 words, confined to the enunciation of basic, permanent principles in broad and generous terms. The U.S. constitution does no more than organize basic political institutions: it describes the framework of government concisely, leaving the details to legislative action, and the door is left open for change and adaptation through usage and interpretation. It also limits all government by guarantees of individual liberties and provides for a workable method of amendment, thus allowing for future alterations.

Another reason for the constitution's success is that it was rooted solidly in historical experience, containing little when written that was experimental or new. Its authors drew their ideas from English law and practice, from colonial experiences, from the state constitutions and the Articles of Confederation and did not borrow from sources unrelated to their experience. In a real sense, the constitution was an outgrowth, and indeed the climax, as man's most recent victory in the ancient struggle for liberty, of the great traditions of the English common law. It was not imposed by a foreign power or dictated from above by a ruler, nor was it, as with many later constitutions, the product of military defeat. It was an act of free will, a triumph of human reason, so it seemed, in an age of European turmoil, a symbol of good government in that great epoch of modern political reconstruction. The document also served as a powerful centre of loyalty, in a pluralistic nation of nations, for the diverse peoples who make up the U.S. population.

**Judicial Review.**—The constitution is, in the last analysis, interpreted by the courts, the United States supreme court acting as the final court of appeal from the state courts and the lower federal courts (see SUPREME COURT OF THE UNITED STATES, THE). Strictly speaking, the constitution means what the judges say it means, as Charles Evans Hughes once said, and U.S. constitutional law consists of a vast body of judicial rulings interpreting the constitution. But in a broader sense, the constitution acquires meaning at the hands of all who use it. Thus congress on innumerable occasions has given new scope to the document through the enactment of statutes, such as those creating the great executive departments, the federal courts, territories and states, or those controlling succession to the presidency or those setting up the executive budget system. The chief executive likewise has contributed to constitutional interpretation over the years, as in the development of the executive agreement as an instrument of foreign policy. Furthermore, many key elements of U.S. government which in fact rise to the dignity of constitutional arrangements

are mainly a matter of custom, existing outside the letter of the constitution altogether. The English call these customs and usages "conventions" of the constitution. Perhaps the best example of an American constitutional convention is the system of political parties, with their elaborate organization and procedures for the fighting of campaigns. The presidential cabinet is largely conventional, as is the actual operation of the electoral college system. Very little indeed would be learned from a mere reading of the document about how the president is actually nominated and elected.

The power of U.S. courts to rule on the constitutionality of legislation, and to refuse to enforce legislation which in their judgment violates the constitution, has come to be known as judicial review (*q.v.*). Few courts in the world have this extraordinary power. Thus a statute passed by parliament may indeed violate the constitution of the realm, *e.g.*, a gross statutory invasion of free speech, but no English court has the right to refuse to enforce it on constitutional grounds. Parliament is sovereign; but in the United States the constitution, as construed by the courts and as the embodiment of the will of the whole people, is sovereign. This great power is, however, not explicitly mentioned in the constitution and is itself a product of judicial construction. While prerevolutionary state appellate courts had occasionally exercised the power of judicial review, the definitive assertion regarding federal judicial review was made by the U.S. supreme court in 1803 in *Marbury v. Madison*. Here Chief Justice John Marshall reasoned that since the constitution is the supreme law of the land (it says as much in art. vi), and since it is the province of the court to uphold the law, it follows that when a statute is inconsistent with a provision of the constitution the latter must be preferred to the former because it declares the law of superior obligation. Without judicial review, he argued, a written constitution would be quite futile as a means of limiting the abuses of governmental power.

While the supreme court possesses the ultimate power of declaring federal and state legislation invalid on constitutional grounds, it has exercised it with great restraint. Only about 80 federal statutes had by the early 1960s been so declared, though the number of state statutes held invalid was much larger. The court will exercise this power only if necessary to decide cases and controversies and will not, as a few state courts will, give mere advice to congress or the executive in the form of advisory opinions. Judicial review, therefore, always grows out of concrete litigation where the rights of adversary parties are actually involved. Furthermore, the supreme court imposes a number of its own restraints upon the exercise of judicial review. It always begins with the assumption that the legislative body did not intend to violate the constitution when it adopted the challenged statute. Therefore the burden of proof rests upon the party who questions the validity of the statute. If the court can possibly decide the case without ruling on the constitutionality of the statute, it will prefer to do so; it comes to constitutional questions last, not first, and seeks to dispose of cases on minimal grounds. If a statute is susceptible of any reasonable interpretation which will save it, the court will adopt that interpretation. In cases of reasonable doubt, the constitutionality of legislation will be upheld. The court will not hold a statute invalid on such vague grounds as that it violates natural justice, or the spirit of the constitution or the principles of republicanism.

The court takes a strict view of the question of who is eligible to raise constitutional questions to litigation: to be able to sue in court, a party must have a direct and substantial interest at stake. Thus it was held that a mere citizen and lawyer has insufficient interest to question in court the qualifications of a particular justice for his office (*Ex parte Levitt*, 1937). A mere taxpayer qua taxpayer does not have sufficient interest in the United States treasury to attack in court the validity of a federal appropriation act (*Frothingham v. Mellon*, 1923). This rule, which bars federal taxpayer suits, closed the door to a possible flood of litigation which would have been most embarrassing to the government. Further, a statute may be assailed only by one who relies upon an alleged invasion of his own constitutional

rights; one does not have standing to sue in behalf of others.

Finally, the thrust of judicial review is limited by the doctrine of the political, nonjusticiable question. Certain questions arising under the constitution are regarded by the court as being political in character and therefore outside the scope of judicial action. For example, the constitution (iv, 4) declares that "The United States shall guarantee to every State in this Union a Republican Form of Government." But it was early decided (*Luther v. Borden*, 1849) that whether a particular state government is republican in form is for the political branches of the government, *i.e.*, congress and the president, to decide, not the courts. Similarly, the president's duty to see to the faithful execution of the laws is political and therefore not subject to judicial process (*Mississippi v. Johnson*, 1867).

Many military questions, such as the necessity for calling out the militia, and foreign policy questions, *e.g.*, whether the government has recognized a particular foreign government or international boundary or treaty, are considered political in character and therefore nonjusticiable.

**The Separation of Powers.**—The framers of the constitution accepted it as an unchallengeable maxim that the only way to avoid governmental tyranny is to put the legislative, executive and judicial powers in separate departments. This the constitution does in the so-called distributive clauses, declaring that all legislative powers shall be vested in the congress (i), stating that the executive power shall be vested in a president (ii) and placing the judicial power in the hands of the courts (iii). The separation of powers is not only a political theory about the proper organization of government but also a doctrine of constitutional law. It is in accordance with this principle that the courts decline to perform nonjudicial functions and that the exercise by congress of non-legislative functions in connection with legislative investigations tends to be judicially censured.

Since the legislative power is vested in congress, the lawmaking power as a whole cannot be delegated to the president. It was on this theory that the court in 1935 invalidated the National Industrial Recovery act (NIRA), holding that the code-making authority given the president vested in him a virtually unfettered discretion to make law (*Schechter Poultry Corp. v. United States*). This was an unusual holding, since government without large-scale delegations is quite impossible, and as Chief Justice Hughes said in the case, the court had "repeatedly recognized the necessity of adapting legislation to complex conditions involving a host of details with which the national legislature cannot deal directly." This is well illustrated in the great regulatory commissions, such as the Interstate Commerce commission (ICC) and the Federal Communications commission (FCC), established by congress to deal with exceedingly complex and rapidly changing sectors of the economy. All of these agencies operate under the authority of broad delegations of power by congress and necessarily exercise legislative and judicial, as well as administrative, functions (see COMMISSION; REGULATORY AGENCIES).

The steady growth in the power and prestige of the office of president (*q.v.*) became a leading feature of U.S. constitutional government in the 20th century. Contrary to 18th-century assumptions about the separation of powers, the president takes the initiative in proposing legislation, and, indeed, his record as chief executive is more likely to be judged by the success of his legislative program than by any other event. The president possesses vast delegated legislative powers given him in a multitude of statutes. Nevertheless, there are limits to what the president can do, dramatically illustrated in the 1952 holding of the supreme court that Pres. Harry S. Truman's seizure of the steel mills, without statutory authorization, to avoid a strike during the Korean War, was illegal (*Youngstown Sheet & Tube Co. v. Sawyer*). The court ruled that since congress could have authorized the seizure under its various powers, in acting without permission of a statute the president usurped legislative power in violation of the separation of powers principle. It rejected the contention that the president could seize private property under his authority as commander in chief and as chief executive, his power being only to enforce the laws, not to make them. The

constitution clearly vests the lawmaking function in congress, and while congress undoubtedly has the authority to authorize the taking of private property for public use under its power of eminent domain, "the constitution did not subject this law-making power of congress to presidential or military supervision or control."

**The Federal System: National and State Powers.**—A central fact of the U.S. constitution is that it creates a federal system (see also **FEDERAL GOVERNMENT**), under which the powers of government are divided between the national government and the states. This constitutional arrangement is binding upon both parties and not subject to formal change by the national government acting alone. In a true federal system the powers of the local governments are not at the daily mercy of the central government but are derived from a constitution which is equally the source of national powers. The national government has those constitutional powers which are delegated to it; the states, unless they are otherwise restricted, possess all the remaining powers of government (10th amendment). Thus national powers are enumerated, whereas state powers, which are often referred to as the residual powers, are not. Both the national and state governments have a full array of executive and judicial agencies to enforce the laws of their respective legislative bodies. Each has the power to make and enforce its own laws in its own way, though by the second half of the 20th century there had developed a steady growth of co-operation between them in the accomplishment of common purposes, as in the case of the wide variety of social services covered by the grant-in-aid system. All citizens, under the 14th amendment, possess dual citizenship, being simultaneously citizens of both the nation and the state in which they reside. Each citizenship carries with it a bundle of rights and obligations.

While the national government is limited to its enumerated powers, several important facts about these powers must be noted: (1) The national constitution, and statutes and treaties adopted pursuant to it, constitute, in the language of art. vi, "the supreme Law of the Land; . . . any Thing in the Constitution or Laws of any State to the Contrary notwithstanding." This means that any state law, otherwise valid, must yield if contrary to a valid federal law, since the latter is the supreme law of the land. (2) While the national government is limited to the exercise of enumerated powers, these powers are spelled out in broad terms, and the "elastic" clause (i, 8) states that congress shall have the authority "To make all Laws which shall be necessary and proper for carrying into Execution" the various powers vested in the national government by the constitution. It follows that in addition to the specified powers, congress possesses implied powers, a proposition definitively established by Chief Justice John Marshall in the celebrated case of *McCulloch v. Maryland* (1819). Here the supreme court held that congress had the power to incorporate a national bank, in spite of the fact that the constitution is silent on both the creation of corporations and the chartering of banks. It was concluded that since a national bank would facilitate the accomplishment of purposes confided to the national government, such as the collection of taxes and the maintenance of armed forces, congress had a choice of means to achieve these proper ends. "Let the end be legitimate," said the chief justice, "let it be within the scope of the constitution, and all means which are appropriate, which are plainly adapted to that end, which are not prohibited, but consist with the letter and spirit of the constitution, are constitutional." This doctrine of implied powers became a powerful force in supplying the constitutional basis for the steady growth, over the years, of national power. (3) In the field of foreign affairs the doctrine of enumerated powers breaks down almost entirely, since the supreme court takes the view that whether enumerated or not, the national government, from the very nature of things, has full responsibility over foreign affairs and has the inherent power to do all things which sovereign nations customarily do in this area. Thus the court early took the position that the national government has unlimited power to exclude aliens from the country, and very wide authority to deport them, on any terms it desires, though the constitution says

not a word on this subject (see **ALIEN**). In the *Chinese Exclusion* case (1889) the court said: "While under our constitution and form of government the great mass of local matters is controlled by local authorities, the United States, in their relation to foreign countries and their subjects or citizens, are one nation, invested with powers which belong to independent nations, the exercise of which can be invoked for the maintenance of its absolute independence and security throughout its entire territory." And Justice Stephen Field added: "For local interests the several states of the union exist, but for national purposes, embracing our relations with foreign nations, we are but one people, one nation, one power." In fact, in 1936, in a decision upholding an arms embargo, the court went so far as to say that in contrast with the enumerated powers exercised internally, the federal powers of external sovereignty do not even depend upon affirmative grants of the constitution, though of course some of these powers, but by no means all of them, are enumerated (*United States v. Curtiss-Wright Export Corp.*).

Whether the national government or the states have overstepped the boundaries of their constitutional authority is ultimately a legal question for the supreme court to decide, if the issues can be brought to it in proper litigation. In this sense the supreme court may be said to be the umpire of the federal system. It has on occasion declared acts of congress invalid as invading the reserved powers of the states, and it has often held state laws unconstitutional as being contrary to the supreme law of the land. Nevertheless, though the supreme court is the umpire of the federal system, it is chosen by only one side; it is a national, and in no sense at all a state, institution, and on the whole its leanings are toward the national position. While the court was states-minded during some periods, as during the chief justiceship of Roger B. Taney (1836-64) and in the period 1933-36, for the most part it was willing, in the course of U.S. history, to sanction an ever-expanding conception of national power. This was especially true after 1937, when the court began to uphold leading New Deal reform and regulatory measures. Thus, while the constitution cannot be formally changed without the concurrence of the states, if congress passes a law, and the president signs it and the supreme court holds it constitutional, there is, as a matter of law, no way of questioning the validity of the new enactment. As part of the supreme law of the land it is binding upon the states, whether or not they agree that it falls within the proper scope of the national government.

In still another sense the supreme court is the umpire of the federal system, for it is given original jurisdiction by the constitution (iii, 2) over disputes between the states. The last recourse a state has in such circumstances is to sue in the supreme court, and by the late 1950s every state in the union but one had been at least once a plaintiff or defendant in such lawsuits, involving such difficult questions as boundaries, debts, water rights and water pollution. The court performs an important function in successfully adjudicating disputes, which might lead to the use of force in the case of independent nations similarly involved.

**Federalism and the Commerce Clause.**—The competing concepts of federal supremacy and states' rights were brought early in U.S. history into sharp focus in the field of commercial regulation. The commerce clause (i, 8) of the constitution simply authorizes congress "To regulate Commerce with foreign Nations, and among the several States, and with the Indian Tribes." In the formative years of the republic the supreme court took a broad view of national power under this clause, as in the seminal case of *Gibbons v. Ogden* (1824), which held that the power of congress over commerce includes navigation. As new methods of interstate transportation and communication came into use, ranging from the stagecoach, the railroad and the telegraph line to the ticker tape, trucking, radio, the airplane and television, the court interpreted the national power to keep pace with the times.

But on occasion the supreme court followed a theory of dual federalism, later abandoned, according to which the mere existence of states is regarded as interposing an independent limitation upon the exercise of the powers duly delegated to the national government; i.e., the national government is supreme only to the point

where reserved state power might be invaded. To put it differently, the 10th amendment, in this view, was regarded as a judicially enforceable limitation on the supremacy clause. Perhaps the most famous examples of the use of the doctrine of dual federalism were two child labour cases, *Hammer v. Dagenhart* (1918) and *Bailey v. Drexel Furniture Co.* (1922), in which the supreme court invalidated acts of congress which barred the products of child labour from the channels of interstate commerce and which taxed the net profits of the employers of such labour. The dual federalism doctrine reached its high-water mark during the years 1933-36, when the court held unconstitutional a significant portion of the early New Deal legislation, as in the invalidation of the Guffey Coal act (*Carter v. Carter Coal Co.*, 1936) and the Railroad Retirement act of 1934 (*Railroad Retirement Board v. Alton Railroad Co.*, 1935). The theory of dual federalism was, however, abandoned by the court in 1937, when it upheld the National Labor Relations act, the amended Railway Labor act and other New Deal statutes. The court began to hold, in effect, that in the exercise of its delegated powers the national government is supreme, as the supremacy clause says, so that as far as these powers go there are no states' rights. Perhaps the best example of this reassertion of the national supremacy doctrine was the case (*United States v. Darby Lumber Co.*, 1941) upholding the Fair Labor Standards act of 1938, which statute fixed minimum wages and maximum hours for all employees engaged in the production of goods for interstate commerce. The commerce clause, the court said a few years later, was not designed "to render the nation powerless to defend itself against economic forces that congress decrees inimical or destructive of the national economy. Rather it is an affirmative power commensurate with the national needs. It is unrestricted by contrary state laws or private contracts." (*North American Co. v. S.E.C.*, 1946.)

Nevertheless, the court did not regard the commerce power as being exclusively national, the states being up to a point conceded the right also to regulate interstate commerce. The problem was to locate the point. After considerable fumbling the court hit upon a formula (*Cooley v. Board of Wardens of the Port of Philadelphia*, 1851). Upholding state regulation of pilotage, the court ruled that the states may regulate those aspects of interstate commerce which congress has not attempted to regulate and which do not "imperatively [demand] a single uniform rule" for the whole country. Where congress has been silent and diversity of treatment is desirable, the states enjoy the power of concurrent regulation; but where uniformity of treatment is imperative, the power of congress is "exclusive." The application of this formula was, following its enunciation, the subject of an immense number of decisions. Under it the court sustained a wide variety of state tax and regulatory measures as applied to interstate commerce. In the absence of federal legislation, for example, and in the interests of safety and economy, a state may go a long way in regulating interstate highway traffic, for this is of peculiarly local concern. The tax measures involving a wide variety of state imposts on the sale, use or storage of goods which were shipped interstate before or after the taxing event were similarly sustained.

But it is familiar doctrine that a state may not regulate an aspect of interstate commerce at all if congress has pre-empted the field. To the extent that congress has stated a policy, state legislation which is inconsistent with it is invalid. However, unless congress spells out its purpose of pre-empting a field by specific language, which it rarely does, whether or not federal legislation occupies a field to the point of excluding state legislation is a matter for the court to decide, and this question has accordingly come up many times, especially in cases involving labour relations. In balancing competing local and national needs in commerce, the supreme court exercises a wide discretion. The applicable legal formulas are broad and ill-defined, and the justices have ample scope for the consideration of the equities of the public policy questions which the cases present.

**The Guarantee of Individual Rights.**—The national government is obliged by many provisions of the constitution to respect the basic rights of man. (For a detailed discussion of these rights see CIVIL LIBERTIES; NATURAL RIGHTS.) Some civil rights

limitations were imposed on this government in the original document, notably in the provisions guaranteeing the writ of habeas corpus and forbidding bills of attainder (legislative trials) and ex post facto laws, (i, 9) and guaranteeing trial by jury in criminal cases (iii, 2). But the most significant limitations of this character upon the national government were added in 1791 with the ratification of the first ten amendments, the Bill of Rights (see BILL OF RIGHTS, UNITED STATES). Here are guaranteed basic rights of conscience, such as freedom of religion, speech, press and petition; fundamental guarantees of fair procedure for persons accused of crime, such as protection against unreasonable searches and seizures, compulsory self-incrimination and excessive bail, a speedy and public trial by a local, impartial jury before an impartial judge and representation by counsel; and rights of private property, as in the provision that private property shall not be taken for public use without just compensation.

For the protection of such rights as these against state, as opposed to federal, action, the citizen originally had to look to the state constitution, each state constitution possessing a more or less elaborate bill of rights enforceable by the state courts. But an important new federal limitation on the states was added to the national constitution with the ratification, in 1868, of the 14th amendment, by which the states are forbidden to deny any person life, liberty or property without due process of law or to deny to any person the equal protection of the laws (see also DUE PROCESS). By a process of interpretation at the hands of the supreme court these two clauses took on increased meaning.

The liberty which the due process clause of the 14th amendment guarantees against state action has been held to include the liberties of religion, speech and press which the 1st amendment protects against violation by the national government. Similarly, some of the guarantees of a fair trial in other parts of the federal Bill of Rights, such as the defendant's right to an impartial judge and the assistance of counsel, have also been judicially absorbed into the 14th amendment. Indeed, a minority of supreme court justices argued that the 14th amendment was intended to incorporate all limitations upon the states all the provisions of the federal Bill of Rights. But a majority of the court clung to the position that not all of the guarantees of the federal Bill of Rights are so fundamental to justice that they are required by due process of law. Thus, to cite an early example, the 5th amendment guarantee of indictment by grand jury was held inapplicable to the states (*Hurtado v. California*, 1884), and in fact most states abandoned this type of indictment in favour of allowing the public prosecutor to bring criminal charges. A number of the purely procedural guarantees of the federal Bill of Rights have been held inapplicable to the states, although they of course bind the agencies of the national government.

The other great limitation on the states in the 14th amendment that no state shall deny any person within its jurisdiction the equal protection of the laws, has a long and important history in U.S. constitutional law. Thus over the years the supreme court has set aside many criminal convictions of Negroes on the ground that the state courts which convicted them arbitrarily and systematically excluded Negroes from their juries, this being construed as a denial of equal justice to members of the excluded group. By all odds the most spectacular and controversial application of the equal protection clause came on May 17, 1954, when the court ruled that states which segregated white and Negro children in the public schools violated the constitution (*Brown v. Board of Education*). In so ruling the court set aside the 1896 ruling (*Plessy v. Ferguson*) that "separate but equal" facilities satisfied the command of the 14th amendment, holding by unanimous vote that separate educational facilities, by creating feelings of inferiority, are inherently unequal. After a year of further study the court fashioned a decree which ordered that racial integration in the public schools should be handled at the local level by the federal district courts, which were directed to take local conditions into account and to proceed, in the classical language of equity, with all deliberate speed.

It remains to be noted that none of the great constitutional rights of conscience, however vital to a free society, is absolute

in character. Thus, while the constitutional guarantee of freedom of religion goes a long way, it does not serve to protect acts judged to be morally licentious, such as polygamous marriages. Children cannot be required to execute a flag salute which is forbidden by religious belief (*West Virginia State Board of Education v. Barnette*, 1943), but parents are not free to ignore child labour laws on the ground of religious practice (*Prince v. Massachusetts*, 1944). Similarly, freedom of speech, often defended by the courts, does not extend to the seditious utterances of a conspiracy which, in the considered opinion of congress, poses a clear and present danger to the safety of the republic (*Dennis v. United States*, 1951). But the court has emphasized that the act of congress on this subject, the Smith act, does not forbid mere advocacy of abstract doctrine but only incitement to action designed to accomplish the illegal purpose of overthrowing the government (*Yates v. United States*, 1957). The state is not free to license the privilege of giving a speech (*Thomas v. Collins*, 1945), but it may punish utterance of "fighting words" which may lead to breaches of the peace (*Chaplinsky v. New Hampshire*, 1942) or the publication of obscene matter (*Roth v. United States*, 1957).

There was much concern at mid-20th century with the rights of persons accused of crime. The right of an indigent defendant to representation by counsel has been judicially underscored, and the courts appeared increasingly meticulous to safeguard the right to reasonable bail and the right to a fair trial, including a public, speedy trial before an unbiased judge and a jury free of mob domination. In 1966 a Cleveland osteopath, Samuel H. Sheppard, won a reversal by the U.S. supreme court of his conviction on the grounds that his trial was prejudiced by excessive newspaper publicity. The uses of the writ of habeas corpus were steadily expanded. Some rights, such as the privilege against self-incrimination, came under heavy public fire, but the proposition that no one should be compelled to testify himself into jail retained its vitality in U.S. courts. Everywhere, in criminal cases, the burden of proof remained on the prosecution, and the accused carried with him the presumption of innocence.

**Taxation.**—The constitution delegates to congress an extremely broad power "To lay and collect Taxes, Duties, Imposts and Excises" (i, 8). It forbids congress to tax exports and requires that direct taxes must be apportioned among the states according to population (i, 9). When the supreme court ruled in 1895, contrary to a century of precedent, that taxes on incomes derived from property were in contemplation of law direct taxes, thus invalidating the federal income tax law of 1894 (*Pollock v. Farmers Loan & Trust Co.*), the decision was set aside by the ratification in 1913 of the 16th amendment. This relieves congress of the necessity of apportioning income taxes. Whether congress may use its taxing power for regulatory purposes has long been an issue, and occasionally a federal tax has been set aside on the ground that its purpose is not fiscal but is designed to accomplish a purpose which is within the range of state power, as previously noted in the child labour tax case. But such decisions were extremely rare, since almost all taxes have nonfiscal purposes, and accordingly a wide variety of federal taxes having regulatory purposes were approved by the court, such as taxes on narcotic drugs, gambling devices and firearms and the social security taxes. The classic example, of course, was the tariff, the primary historic purpose of which was to protect U.S. economic interests from foreign competition and not simply to raise revenue.

The principal federal constitutional limitation on the taxing power of the states is derived from interpretation of the due process clause of the 14th amendment, the court having ruled that the provision that no state shall deny to any person his property without due process of law means that a state may not levy taxes for nonpublic purposes. But the court is extremely reluctant to dispute with the states as to what constitutes a public purpose, and very few state taxes were ever invalidated on this vague ground. The due process clause was also construed to mean that the states are free to tax persons and property only when they are within the jurisdiction of the taxing authority. It is considered an unreasonable taking of property for a state to levy a tax upon property outside its jurisdiction, since the state does nothing for

the protection of such property. Complicated jurisdictional issues tend to arise particularly in connection with the administration of income and estate taxes, and speaking generally, the court leans in the direction of giving the taxing power of the states the widest possible scope.

**Constitutional Amendment.**—The procedure for amending the United States constitution is outlined in art. v. Amendments may be proposed by a two-thirds vote of both houses of congress or by a convention called by congress on the application of the legislatures of two-thirds of the states. No such convention had by mid-20th century ever been convoked, all amendments having been initiated by congress. The amendment thus proposed must be then ratified either by three-fourths of the state legislatures or by conventions in as many states. It is for congress to decide which of the two methods of ratification shall be used. Only the 21st amendment (1933), repealing the 18th, or prohibition, amendment, was submitted, under the terms in which it was drafted, to the convention method of ratification.

Only 25 amendments had by the late 1960s been added to the constitution since 1789, but since the first ten amendments, which constitute the Bill of Rights, were submitted and ratified (1791) at the same time, and were numbered separately only for purposes of electoral convenience, it could hardly be said that the constitution had in fact been amended 25 times. It would be more accurate to say that it was amended on only 16 occasions. Furthermore, the 11th amendment, which forbids suits against states in federal courts, and the 12th, which corrected an error in the original operation of the electoral college, were purely technical in character, and the 21st amendment merely canceled out the 18th. The most far-reaching were the 13th, 14th and 15th amendments, adopted as a direct consequence of the Northern military victory and occupation of the South in the American Civil War, which imposed important new restraints upon the states.

If a state legislature ratifies a proposed amendment, the supreme court ruled, it may not reconsider its vote later and vote against it; but if the legislature votes against the proposed amendment, it is free to reconsider and vote in favour of it (*Coleman v. Miller*, 1939). One reason given is that the constitution speaks only of ratification, but perhaps a better reason is that the court believes that such questions are political and therefore within the control of congress. If congress wishes to accept a ratification or chooses to ignore a legislature's change of mind, the court believes there is nothing that it can with propriety do about it. In the cases of the 18th, 20th, 21st and 22nd amendments, congress stipulated that each must be ratified within seven years. While art. v is silent on the subject of a time limit for ratifying, the supreme court has ruled that this limiting power is a fair inference from the language of the article, since submission and ratification are successive stages (*Dillon v. Gloss*, 1921).

(D. Fe.)

**CONSTITUTION OF ATHENS**, a treatise by Aristotle (q.v.) or a member of his school, composed at some date be-

tween 329 and 322 B.C., being one of the 158 *Constitutions* collected by him in his later life. Though extant in late antiquity, it was then lost till 1890, when a papyrus copy, not quite complete, was acquired in Egypt for the British museum, and published by F. G. (later Sir Frederick) Kenyon.

**Date and Authorship.**—The British museum's text was composed after 329, since ch. 54, 7 dates a recent change to the archonship of Cephisophon (329–328); but before 322, since the democratic constitution, abolished after Athens' surrender to Antipater in that year, is throughout assumed to be in normal operation. It was thus written during Aristotle's second stay in Athens. It is certain, from quotations and references in extant authors, that this treatise is to be identified with the work known from at least the 3rd century B.C. as Aristotle's *Constitution of Athens*; there remains a possible doubt how far it is a work of his school or of Aristotle himself.

It differs in style from his other works, but these were not meant for general circulation, whereas the *Constitution*, for all its imperfections, seems to be written for a wider public. There are undeniable contradictions between it and the *Politics*, written some time earlier, and most historians think the *Constitution* wrong in fact in the most striking of these discrepancies; i.e., between *Constitution of Athens* 8, 1 which states that Solon introduced the appointment of archons by lot, and *Politics* 1274a which says that Solon did not disturb the existing method of selection. But this is not decisive, and the two works are similar in their general outlook and in the topics they discuss: it may be noted that the statement in *Politics* 1304a, that the Areopagus tightened the constitution as a result of the prestige it had obtained during the Persian Wars, was hardly even intelligible till *Constitution of Athens*, 23, 1–2 was available to explain how the Areopagus saved the situation before the battle of Salamis, and so gained influence without any formal change in the constitution.

The serious doubts are based on the character of the work in general: the inadequacy of parts of it, the odd proportions of the narrative, the trivial anecdotes, and some undoubted errors of judgment have been thought unworthy of Aristotle. But there is serious matter in the *Constitution*, and anecdote enough in the *Politics* and elsewhere, and some inequalities could be due to Aristotle's special interests. The grounds for questioning his authorship are not compelling.

**Contents and Sources.**—The first part (ch. 1–41), a narrative of constitutional developments down to the democratic restoration of 403, ends with a summary list of 11 principal changes. This list, with the bald epitome of Heraclides (an author, otherwise unknown, who preserved excerpts from the *Constitutions*) and a few outside quotations, forms the evidence for the lost beginning. It described the original monarchy; the first change, connected with the legendary Ion, introduced the four old Attic tribes; in the next stage Theseus was dealt with in detail; but for the period from then to the late 7th century there is little indication of what Aristotle wrote. He described Cylon's attempted tyranny (c. 632), and the first surviving sentences deal, by anticipation, with the eventual trial of the descendants of those responsible for the death of Cylon's supporters (see *ALCMAEONIDAE*).

Ch. 2 analyzes the situation which faced Solon (q.v.) in 594, but this is interrupted by 3, devoted mainly to the development of the archonship, and 4, the "constitution of Draco." This last, reflecting much later conditions, is certainly an imaginary construction composed in the late 5th or early 4th century; the mention of it in 41, 2 disturbs the numeration of the list of changes, and it appears to be an addition to the original text, though perhaps one made by the author. In the resumed account of Solon (5–12) he cites, without names, authorities of different political views, basing many of his own judgments on Solon's poems, which are extensively quoted; it is hotly debated whether Solon's laws were also available to consult, or were consulted directly. Ch. 9 agrees with the *Politics* in regarding the popular law court as Solon's main contribution to the development of democracy.

Ch. 13, and other chapters, contain material in annalistic form likely to have derived from the local histories of Athens called

*Attides*: of these the fullest and latest would be that of Androtion (c. 340), whose fragments suggest that Aristotle used his work but sometimes disagreed with it. Six chapters (14–19) give disproportionate space to the Pisistratid tyranny (see *PISISTRATUS*), but Aristotle was interested in tyranny, and the analysis in 16 shows affinities with *Politics* 1314–15. The narrative is substantially that of Herodotus (cited by name in 14, 4), with annalistic additions; Thucydides' account of the murder of Hipparchus is mentioned and rejected, without his name, in 18, 4. The narrative in 20 of the activities of Cleisthenes (q.v.) is again Herodotean, with qualifications; the analysis of his reforms (21), from a different source, agrees with the *Politics* in attaching great importance to Cleisthenes' introduction of new citizens.

Aristotle's treatment of the 5th-century democracy, which he found unattractive, is partial and perfunctory. The reforms of Ephialtes (q.v.) are described in one unilluminating sentence, the rest of the chapter (25) being devoted to a worthless anecdote of Themistocles' participation; the sentence devoted to the trial of the generals after Arginusae in 406 says that all ten were condemned to death (34, 1) when eight were summoned home for trial and only six attended—a misstatement hard to excuse. But there is still valuable annalistic material, notably the early ostracisms (22) and the legislation of the 450s (26, 2–4). The oligarchic movements at the end of the century receive more serious attention. His account of the revolution of the Four Hundred in 411 (29), markedly sympathetic and exculpatory, diverges widely from that of Thucydides, but the latter is the basis for much of 32–33: the source and status of the constitutional drafts in 30–31 is an unsolved puzzle, but in general the revolution cannot have run the course here described. On the rise and fall of the Thirty Tyrants (34, 3–38) he differs from Xenophon in the order of events and other details and is not to be trusted, but his account of the settlement of 403 (39) appears to be based on a genuine document. It has been supposed that these later chapters are heavily influenced by a pamphlet written by some follower of Theramenes (q.v.), but the hypothesis is unnecessary: the sources seem to be as varied here as elsewhere, and the political colour of the account accords with Aristotle's known views.

The second part (42–69) analyzes the contemporary constitution. A full chapter (42) is devoted to the training of the youths of 18–20 years old (*epheboi*), probably because a recent change of system attracted interest. Ch. 43–59 deal with officials appointed by lot, first (43–54) the council (*boule*; q.v.) and the many administrative officials associated with it, whose activities are listed in detail. The council's conduct of public business gives him opportunity to describe (43–44) the procedure of the assembly (*ecclesia*; q.v.), but there is no full discussion of the process of legislation. Ch. 55–59 treat of the archons, first the procedure of their examination and installation, then successively the duties of archon, king, polemarch and *thesmothetae*, primarily the sacrifices they make and the classes of lawsuit over which they preside (see *ARCHON*). Ch. 61 lists more briefly the elected magistrates, almost all military; 62 deals with public pay; the remainder (63–69) describes the law courts, mainly the elaborate mechanisms for assigning jurors to particular courts, and for voting. Most of this detail could have been collected directly, and the hypothesis that Aristotle used some predecessor's work is not now favoured. Where he refers to changes in practice, this rather suggests consultation in the archives of the laws governing the magistrates' duties.

**Value.**—In spite of complaints leveled against the narrative, comparison of Greek histories written before and after the manuscript was discovered in 1890 shows very clearly how much has been gained. In particular, the annalistic items have solved some old problems and added new knowledge. The value of the rest varies not only with the source but with the degree of the author's interest in the period or problem: the discussion of Solon is on an altogether higher plane than that of Pericles. It seems likely that the author was deceived by the official appearance of some spurious or doubtful documents, the so-called constitution of Draco and the constitutional drafts connected with the revolution of the Four Hundred (4; 30–31); and the quality of his

arguments by inference (from later survivals, etc.) has been criticized, perhaps to excess. The importance of the analytic part is beyond question.

**BIBLIOGRAPHY.**—Aristotle, *Constitution of Athens*, ed. by J. E. Sandys, commentary with bibliography covering the earlier stages of controversy (1912); G. Mathieu and B. Haussoullier in the "Budé Series," and introduction (4th ed. 1952); K. von Fritz and E. Kapp, *Aristotle's Constitution of Athens*, Eng. trans. without the Greek text, and commentary (1950).

The most important single book on the subject is still U. von Wilamowitz-Möllendorf's *Aristoteles und Athen* (1893), though he accepted too much as true; G. Busolt and H. Swoboda, *Griechische Staatskunde* (1920–1926), discuss Athenian problems very fully; C. Hignett, *A Constitutional History of Athens* (1952), gives the only good modern account, though perhaps excessively critical of the Aristotelian *Constitution*. (A. As.)

**CONSTITUTIONS, APOSTOLIC**, the largest collection of ecclesiastical law that has survived from early Christianity. The full title is *Ordinances of the Holy Apostles Through Clement*, claiming that these regulations were drawn up by the apostles and transmitted to the church by Clement of Rome. Sometimes the apostles are represented as speaking jointly, sometimes singly. In modern times it is generally admitted that the constitutions were in reality written in Syria about A.D. 380 and that they are the work of one and the same compiler, who seems to have been an Arian and most probably identical with the 4th-century interpolator of St. Ignatius' Epistles.

The first six of the eight books are merely an adaptation of the *Didascalia Apostolorum*, written in Syria about A.D. 250. They deal with Christian ethics, the duties of the clergy, penitential discipline and eucharistic liturgy, widows, deaconesses and orphans, martyrs, fasts and feasts, schism, heresy and Christian burial.

Book vii, 1–32 is nothing more than a paraphrase and enlargement of the *Didache* or *Teaching of the Twelve Apostles* (see APOSTOLIC FATHERS); vii, 33–38 contains a Jewish collection of prayers, 39–45 the rites of baptism and confirmation, and 46–49 other liturgical material, especially ch. 47, which gives the *Gloria in excelsis* as the liturgical morning prayer.

The most important book of the constitutions is book viii. The first two of its chapters seem to be based upon a lost work of Hippolytus of Rome, "Concerning Spiritual Gifts"; ch. 3–22 apparently are based upon the same author's *Apostolic Tradition*, formerly called *Egyptian Church Order*. Book viii, 3–27 provides an elaborate description of the Antiochene liturgy. This part contains (5–15) the so-called Clementine liturgy, which is directed to be used at the consecration of a bishop, a very valuable source for the history of the Mass because of its completeness. There follows a series of canons on various subjects and liturgical formulas in ch. 28–46.

Ch. 47 seems to have been added to the work later, but by the same redactor. It comprises the so-called *Apostolic Canons*, a collection of 85 canons, derived in part from the preceding constitutions, in part from the canons of the councils of Antioch (341) and Laodicea (c. 360). The last of these 85 canons contains a list of biblical books which omits Revelation but places the Apostolic Constitutions and the two Epistles of Clement in the canon of Scripture.

The first edition was published at Venice, by F. Torres, in 1563. The best is that of F. X. Funk, *Didascalia et Constitutiones Apostolorum*, 2 vol. (1905). For a selection of liturgical texts, see J. Quasten, *Florilegium Patristicum*, vol. vii, 4 (1936); the liturgy of book viii is given also in F. E. Brightman, *Liturgies Eastern and Western*, pp. 3–30 (1896). English translations include J. Donaldson, *Ante-Nicene Christian Library*, vol. xvii, pt. 2 (1870), reprinted in *Ante-Nicene Fathers*, vol. vii, pp. 391–505; R. H. Cresswell, *The Liturgy of the Eighth Book of the "Apostolic Constitutions"* (1900).

**BIBLIOGRAPHY.**—F. Nau, in *Dictionnaire de théologie catholique*, vol. 3, col. 1520–37 (1908); H. Leclercq, in *Dictionnaire d'archéologie chrétienne et de liturgie*, vol. 3, col. 2732–95 (1914); J. Quasten, *Patrology II. The Ante-Nicene Literature After Irenaeus* (1953), with later bibliography. (J. Q.)

**CONSUL.** The ancient and modern meanings of the word "consul" must not be confused: in the ancient Roman republic it was the title of the two highest of the ordinary magistrates; in

modern times it survives to designate a public official charged with certain duties in a foreign country.

## THE ROMAN CONSULS

The consulship in ancient Rome arose with the fall of the kings (c. 509 B.C.). It was the deep-seated Roman reverence for the abstract conception of the magistracy, as expressed in the *imperium* (supreme military power) and the *auspicia* (the power of divination), that led to the preservation of the regal power in a qualified form. The two new officials who replaced the king first bore the titles of leaders (*praetores*) and of judges (*iudices*), but soon the title of *consules* (partners) prevailed; and this first example of the collegiate principle assumed the form familiar in the Roman commonwealth. Each of the pair of magistrates could act up to the full powers of the *imperium*, but the dissent of his colleague rendered his decision or his action null and void. At the same time the principle of a merely annual tenure of office was insisted on.

The only body known to us as electing the consuls during the republican period was the *comitia centuriata*, or military assembly (see COMITIA). In the 5th century the consulate was confined to patricians; but after a struggle for office between patricians and plebeians the Licinio-Sextian laws of 367 B.C. enacted that one consul must be a plebeian (see PATRICIANS). In 172 B.C., two plebeian consuls took office for the first time.

In the late republic a man could not be elected consul until two years after he had served as praetor, and re-election was nominally allowed only after ten years' interval. If one consul died during his tenure, his successor was elected; if both died, the patrician senators appointed an *interrex*. The date on which consuls took up office varied from time to time, but after 153 B.C. it was Jan. 1; their names formed the official designation of the ensuing year. The consuls were entitled to an escort of 12 lictors, to the *sella curulis* (see CURULE) and to the *toga praetexta* (purple-bordered robe).

The executive power of the consuls was gradually limited: (1) in jurisdiction, by the grant of appeal (*provocatio*), by the growth of the praetorship and by the publication of law (e.g., the Twelve Tables, 450 B.C.); (2) in administration, by the appointment of the tribunes of the *plebs* (the common people) and by the creation of new magistrates (*censor* [q.v.] in 443, *curule aediles* in 367 B.C.) to take over parts of their functions. The consuls, however, were in a very real sense the heads of the state: for centuries they commanded the Roman army; they governed together with the senate, whose chief executives they were; they were the most regular consultants of this council; they formulated its decrees as edicts; and they brought before the people legislative measures which the senate had approved. They also represented the state to the outer world and introduced foreign envoys to the senate.

Moreover, they retained certain powers of jurisdiction, both administrative and criminal. Their administrative jurisdiction was concerned with financial matters such as claims made by the state and by individuals against one another, when the censors were not in office, and with disputes about property between the cities of Italy. Their criminal jurisdiction was of three kinds: (1) it was their duty to set in motion the criminal law for ordinary, as opposed to political crimes, the reference of such cases to the assembly of the people was effected through their quaestors (see QUAESTOR); (2) when the people and senate, or the senate alone, appointed a special commission (see SENATE, ROMAN), the commissioner named was often a consul; and (3) we find the consul conducting a criminal enquiry raised by a point of international law.

As the consuls were recognized as the heads of the administration abroad as well as at home, their separate departments of administration (*provinciae*) had to be determined and assigned. The method of assignment varied. Foreign wars often demanded the attention of both consuls. In this case the regular army of four legions was usually divided between them. When it was necessary that both armies should co-operate, the principle of rotation was adopted, each consul having the command for a single

day. During the great period of conquest from 264 to 146 B.C. Italy was generally one of the consular "provinces," some foreign country the other; and when at the close of this period Italy was at peace, this distinction approximated to one between civil and military command. The consuls settled their departments by agreement or by lot (*comparatio, sortitio*); the power of declaring what should be the consular *provinciae* was usurped by the senate (see SENATE, ROMAN). But the home officials invested with the *imperium* proved insufficient for the military needs of the empire, and the system of prolonging the command (*prorogatio imperii*) grew up (see PROVINCE, ROMAN). The former magistrates after their year of office began to go abroad to undertake a year of provincial government and, in some special cases, appointments were made by law for longer periods. Technically the provinces might still be consular, actually they were proconsular. The separation of military from civil power became general after Sulla, and in 52 B.C. the Lex Pompeia established a five years' interval between home and foreign command.

Since the theory of the persistence of the republican constitution was of the essence of the principate, the consuls lost little of their outward position and dignity under the Caesars. In the interval between the death or deposition of one *princeps* ("emperor") and the appointment of another the consuls resumed their normal position as the heads of the state. As the presidents of the senate, who after A.D. 14 elected them *de facto* to their office, they directed that high criminal jurisdiction which the senate of this period assumed. A restored power of jurisdiction is indeed one of the features of their position during this time, and it is probable that the civil appeals which came to the senate were delegated to the consuls. They acted for a time as delegates to the *princeps* in such juridical matters as trusts and guardianship. The consulship was also a preparation for some of the most important governmental posts in the provinces, and for the prefecture of the city. The tenure of the office was progressively shortened. In the early principate the consuls held office for six months, later for four to two months. The consuls appointed for Jan. 1 were called *ordinarii* (chosen at the ordinary time), the others *suffecti* (chosen in the course of the year), and the whole year was dated by the names of the former. This distinction continued in the empire of Constantine and his successors. The *ordinarii* were nominated by the emperor or emperors, one for the west and one for the east; the *suffecti* by the senates of Rome or of Constantinople, their appointment being ratified by the emperor. The consulship was still the greatest dignity which the empire had to bestow, and the pomp and ceremony of the office increased in proportion to the decline in its actual power. The entry of the consuls into office was celebrated by a great procession, by games given to the people and by a distribution of gifts. But the senates over which they presided were little more than municipal councils, and the justice which they meted out had dwindled down to formal and uncontested acts. The last consul born in a private station was Basilus in the east in A.D. 541. But the emperors continued to bear the title for some time longer.

### CONSULS IN MODERN TIMES

A consul in the 20th century is a public officer authorized by the state whose commission he bears to protect the interests and to foster the commercial affairs of its subjects in a foreign country, and formally permitted by the government of the country wherein he resides to perform the duties which are specified in his commission. A consul, as such, is not invested with any diplomatic character and cannot enter on his official duties until permission, usually in the form of an exequatur, has been granted to him by the authorities of the state to which his nomination has been communicated by his own government although he is often pro-

visionally recognized pending its issue. The exequatur may be revoked at any time at the discretion of the government of the country in which he resides.

**History.**—The title of consul, in the sense in which it is used in international law, is derived from that of certain magistrates in the cities of medieval Italy, Provence and Languedoc, charged with the settlement of trade disputes whether by sea or land (*consules mercatorum* or mercantile consuls, *consules artis maris* or maritime consuls, etc.). With the growth of trade it early became convenient to appoint agents with similar powers in foreign parts, and these often, though not invariably, were styled consuls (*consules in partibus ultramarinis*, consuls in overseas parts).

It was not until the beginning of the 19th century that the system developed universally. Hitherto consuls had, for the most part, been businessmen with no special qualification in regard to training; but the French system, under which the consular service had been long established as part of the general civil service of the country, was gradually adopted by other nations; though, as in France, consuls not belonging to the regular service and having an inferior status continued to be appointed. In Great Britain the consular service was organized in 1825; in France the series of ordinances and laws by which its modern constitution was fixed began in 1833. In Germany a well-organized consular system followed the establishment of the united empire. The functions, duties and privileges of French and German consuls do not differ materially from those of British consuls; but there is a great difference in the organization and personnel of the various consular services. In the United Kingdom, France, Italy, the United States, Belgium and other countries, members of the consular and diplomatic services are interchangeable. In France the diplomatic and consular services were amalgamated by decrees of July 10, 1880, and April 27, 1883, and other countries gradually followed this example.

Few countries can afford the cost of career officers at every consular post and the corps of career officials is therefore supplemented by honorary officers, usually residents engaged in trade, who are citizens of the country which nominates them, or in which they reside.

**Privilege.**—Whereas diplomatic privileges and immunities are clearly defined, those to be enjoyed by consuls are not finally established in all their details, and some differences of opinion exist about some of these. At the end of the 18th century and the beginning of the 19th the question whether consuls were public ministers and thus entitled to all the privileges and immunities of diplomatic representatives was debated. After some divergence of opinion, the view prevailed generally that consuls had no representative character and could not, therefore, claim the general immunity and exterritoriality attaching to diplomatic representatives. From this it was concluded at one time, particularly in the United Kingdom, that consuls possessed no privileges or immunities at all. They are, however, charged by their governments with the carrying out of important duties and it became generally recognized that under international law consuls enjoy such protection and immunity as are required for performance of these duties. It is not therefore, disputed that the archives and all other official documents and papers kept in a consulate and all correspondence between the consul and his government are inviolable. Consular officers and their employees are entitled to refuse production of such documents in the local courts or to give evidence relating to matters within the scope of their official duties. Furthermore, it is generally admitted that consular officers are not liable in criminal or civil proceedings for acts performed in their official capacity falling within the functions of consuls under international law. This protection does not cover the private activities of consuls, and numerous instances have been recorded where consuls were arrested for private debts. The status and privileges of consuls and the functions which they are entitled to perform are frequently specified in international agreements often called consular conventions. Consuls are, however, often exempt from all kinds of rates and taxes, and from personal taxes. They are exempt from billeting and military service and have the right to exhibit their national arms and flag over the door of their offices. (E. J. F.; X.)

## UNITED STATES

The U.S. constitution provides (art. ii, sec. 2) that the president "shall nominate, and by and with the Advice and Consent of the Senate, shall appoint Ambassadors, other public Ministers, and Consuls. . . ." United States consuls served abroad from the foundation of the republic, and even before, but it was not until the early 20th century that a career, nonpolitical consular service was established. Prior thereto consular appointments were political favours, subject to patronage. The act of April 14, 1792, first defined the duties of consuls; these related primarily to the protection of U.S. citizens and property. An act of 1856 raised some consular salaries and defined powers and rights of consular officers in greater detail, but still no career service was provided. The act of April 5, 1906, classified officers in nine grades, provided for inspectors, required that fees be placed on a strict accounting basis, and made performance of notarial services obligatory. By executive order of June 27, 1906, Pres. Theodore Roosevelt placed the consular service under operation of the civil service law, thereby establishing a career service.

The Rogers act of 1924 merged the consular and diplomatic services into a single, unified professional U.S. foreign service under the direction and supervision of the secretary of state. This law established the principle of interchangeability of consular and diplomatic assignments for foreign service officers which was observed generally thereafter. Provision was made for the selection of new officers by competitive written and oral examinations.

The Foreign Service act of 1946 was designed to improve the organization and administration of the service. In addition, the 11 classes of officers under the 1924 act were reduced to 6, plus the new class of career minister. Officers' salaries included allowances for quarters, cost of living, representation and hardship conditions. The interchangeability principle for foreign service officers was preserved. The act also created a foreign service staff corps whose officers were intended to be technical specialists primarily throughout their careers. Consular officers serving permanently as such were to be staff corps officers. The number of classes was increased to ten in 1956, and the foreign service was integrated with the home service of the department of state. In the late 1950s salaries ranged from \$4,730 for a foreign service officer 8th class to \$19,250 for a career minister and \$20,000 for the new rank of career ambassador. Staff salaries ranged up to \$11,965.

Four consular titles are in use: consul general, consul, vice-consul and consular agent. Consuls general and consuls are commissioned by the president and approved by the senate, as are foreign service officer vice-consuls. Staff officer vice-consuls are commissioned by the secretary of state without senatorial approval. All must be U.S. citizens; consular agents, appointed by the secretary of state, need not be. Consular posts are designated as consulates general, consulates or consular agencies. Those located at diplomatic missions are referred to administratively as consular sections of the missions. Where several consular posts exist in a country (e.g., Great Britain, France, Germany, Italy, Spain, Japan) the ranking consular officer therein is designated "supervising consul general," responsible for co-ordinating the entire consular program on a country-wide basis.

Technical consular functions are prescribed by law and regulation. These include issuance, extension, amendment and renewal of passports; original determination of validity of claims to citizenship; issuance and refusal of visas to aliens; performance of notarial services; protection of U.S. citizens and property; assistance to seamen and shipping; documentation of imports. Consular officers also engage in reporting, representation, negotiation, and promotion of commerce and perform services for many other government departments and agencies.

The bureau of security and consular affairs in the department of state supervises and co-ordinates the activities of three offices therein—passport office, visa office and office of protective services—which provide the requisite technical guidance and assistance to consular officers in the field.

The U.S. relinquished its former jurisdiction over civil and

criminal cases in which a U.S. citizen was a defendant in China, Ethiopia, Japan, Iran, Thailand and Turkey. Its extraterritorial consular courts therein were closed accordingly. The last two such courts in Tangier and Casablanca were closed in 1956.

See the draft code on the legal functions of consuls, in *American Journal of International Law*, supplement, vol. 26, pp. 189-450 (1932); *Foreign Service Journal* (monthly), Washington, D.C.

(F. J. MN.; X.)

## UNITED KINGDOM

Until the year 1825 British consuls were usually merchants engaged in trade in the foreign countries in which they acted as consuls, and their remuneration consisted entirely of fees. An act of 1825 organized the consular service as a branch of the civil service with payment by a fixed salary instead of by fees; consuls were also forbidden to engage in trade, and the management of the service was put under the control of a separate department of the foreign office, created for the purpose. The restriction as to engaging in trade was withdrawn in 1832, except for salaried members of the British consular service.

Specialized consular services for China, Japan, Thailand (Siam) and the Levant were formed later. In 1903 the general consular service was organized as a self-contained career service. In 1919 the administrative control of the consular service was transferred from the consular department of the foreign office to the department of overseas trade (a joint department of the foreign office and the board of trade). The specialized regional consular services were merged with the general consular service into a single entity in 1934. By the reforms of 1943 the consular service and the commercial diplomatic service were amalgamated with the foreign office and diplomatic service to form a single foreign service. Consular ranks descend from consul general, consul and vice-consul, down to pro-consul. In some places honorary consuls are appointed. Under a system inaugurated in 1913 and subsequently developed, a corps of inspectors has the duty of visiting consular posts all over the world and reporting to the foreign office on personnel, work and conditions in them.

The many duties of British consuls are given in detail in the official *Instructions*. They may briefly be summarized as follows: To protect British subjects and to assist them in distress; to watch and, where necessary, to represent British interests; to act as notaries public and as registrars (e.g., for births, deaths and marriages); to administer the Merchant Shipping acts with regard to British ships and seamen, wrecks and collisions; to report fully on the trade and commerce of the district; and generally to facilitate and to uphold the rightful interests of British traders. Under the Merchant Shipping acts of 1894 and 1906, British consuls have certain statutory duties and powers relating mainly to the welfare of the crew and to discipline on board. At a foreign port engagements and discharges of seamen must be sanctioned by the consul, who arranges suitable hospital treatment for sick seamen and takes charge of their wages. The consul also provides for the subsistence of seamen who are shipwrecked or left behind; they are generally sent home in the first British ship. Complaints by crews as to their treatment on board are investigated by the consul, who enters a statement in the log book and reports to the ministry of transport. When an offense has been committed on the high seas by British seamen, the consul may make inquiry on oath and send home the offender and the witnesses. In certain cases a consul can summon a naval court to deal with a grave offense or casualty, but the procedure is cumbersome, and effect cannot always be given to the findings. The master of every British ship not carrying passengers is obliged to deposit at the consular office at a port where there is a British consul the copy of the articles of agreement with the crew, if the ship remains 48 hours in port.

The board of trade is authorized to communicate with and give instructions to consuls on all questions relating to commercial intelligence and the development of British overseas trade. Consuls report direct to the board of trade on commercial matters, and they are also, for the commercial side of their work, under the general supervision of the senior commercial officer attached to the embassy or legation to the country in which they are

stationed. See also FOREIGN SERVICE; DIPLOMACY.

It is the duty of a consul to deal to the best of his ability with all questions on commercial subjects addressed to him not only by the departments at home but also by individual British traders. He is expected also to furnish on his own initiative reports on matters of commercial interest. In addition to such questions as tariffs, customs regulations, patents, regulations relating to commercial travelers and their samples, the formation of industrial syndicates, legislation regarding transport, the organization of international exhibitions and fairs, aerial navigation, labour legislation, crops and fishery matters, the consul is expected to report regularly on changes in the general financial and other conditions affecting local trade and industry; openings for the sale of British goods and effects of foreign competition; the development and organization of local industry, trade, finance, public utilities and means of transport; and the development of local export trade in raw materials.

As regards extraterritorial jurisdiction her majesty's courts have jurisdiction over certain classes of foreign nationals in Kuwait, Bahrain, Qatar, the Trucial states and Muscat and Oman.

Her majesty's government renounced as from Dec. 6, 1956, the jurisdiction possessed in the former Spanish zone of Morocco (see *The Morocco [Former Spanish Zone] Order, 1956*), which also brought to an end the functions for the court for Morocco.

(E. J. P.; X.)

**"CONSULATE OF THE SEA,"** a celebrated collection of maritime customs and ordinances in the Catalan language, published at Barcelona, Spain, in the latter part of the 15th century. Its proper title is *The Book of the Consulate*, or in Catalan *Lo Libre de Consolat*, the name being derived from the fact that it embodied the rules of law followed in the maritime cities of the Mediterranean coast by the commercial judges known generally as consuls (*q.v.*).

The edition of 1494, which is justly regarded as the first edition of the *Book of the Consulate*, contains (1) a code of procedure issued by the kings of Aragon for the guidance of the courts of the consuls of the sea; (2) a collection of ancient customs of the sea; and (3) a body of ordinances for the government of cruisers of war. A colophon states that "the book commonly called the *Book of the Consulate* ends here"; after which there follows *The Acceptations*, which purports to record that the previous chapters and ordinances had been approved by the Roman people in the 11th century, and by various princes and peoples in the 12th and 13th centuries, but this document clearly has no proper reference to the *Book of the Consulate*, and is, in fact, of no historical value. See also MARITIME LAW.

**CONSUMER'S SURPLUS**, a term used by economists to denote the benefit to a consumer from being able to buy an item at the current price when it is actually worth much more than that price to him. A ten-cent telephone call, for example, may sometimes be worth many times its actual cost. In general, a consumer will buy only a specific amount of a given commodity because one more unit would not be worth the price, but most of the units that he does buy are actually worth more to him, and he would have bought them even at a higher price. The sum of the differences between what he would have paid and what he does pay is a measure of the consumer surplus.

This concept was used by A. J. E. J. Dupuit in 1844 and popularized by Alfred Marshall in 1890 as a means of measuring the degree to which an increase in price caused by a tax affects the consumer and thus to show the government how to minimize the tax burden on the consumer. In the same way one could measure the benefit to consumers from a subsidy to determine whether it was worth the cost.

Early in the 20th century the concept of consumer's surplus fell into disrepute among economists because of certain difficulties in measuring its amount and because of certain errors into which Marshall himself had fallen in adding up the consumer's surplus of different people and in adding the consumer's surpluses that an individual got from different items. This is troublesome because the consumer's surplus obtained from one item is not independent of the availability and price of other items. Further-

more, the measure of consumer's surplus by the amount of money a consumer would give rather than have a price increase is in general different from the amount of money he would have to be paid in lieu of price reduction, and these were both considered to be measures of the same thing. However, in the 1940s some of the difficulties were cleared up and consumer's surplus became a more respectable part of welfare economics, largely as a result of the initiative of John R. Hicks.

(A. P. L.R.)

**CONSUMPTION.** By origin and usage the word consumption implies the destruction in use of goods and services normally produced by deliberate human effort. In modern economic writing it is synonymous with the final appropriation of goods and services for use or ownership by the general public. In this sense the general public may include persons who act either directly as private persons or indirectly as members of some corporate body, such as a division of local government, empowered to distribute the benefits of consumption according to agreed rules. In addition to items such as food and fuel, which are usually destroyed in use shortly after appropriation by final consumers, the act of consumption includes the acquisition of many others, such as furniture or vehicles, which may be extremely durable, and some, such as works of art, which may increase in value with the passage of time.

Final consumption may be contrasted with the physical disappearance or transformation of fuel, raw materials and other intermediate products of human industry when these are combined to produce further commodities. Final consumption is also to be distinguished from the purchase by industry of fixed assets, such as buildings and machinery. This last activity is known as capital formation, and the wearing out of the stock of capital during the process of commodity production is known as depreciation, again in distinction from the direct consumption of the final commodities themselves.

In the internationally agreed framework of modern national income accounting, the gross national expenditure (including depreciation) of an economy is made up as shown in Table I, which gives the relevant figures for the United Kingdom in 1960. These may be taken as fairly typical for a modern industrial economy, and they show that final consumption accounts for about 88% of the gross domestic product.

TABLE I.—Consumption Expenditure in the United Kingdom National Accounts, 1960

Expenditure	in 2000,000	Per cent
<i>Consumption expenditure</i>		
Consumers' expenditure on goods and services	16,608	70
Government current expenditure on goods and services (including defense)	4,189	18
	20,797	88
<i>Capital expenditure</i>		
Net investment in fixed assets by government and industry	2,088	9
Depreciation of fixed assets	2,615	8
Accumulation of stocks	591	3
	4,694	20
<i>External transactions</i>		
Exports of goods and services	5,102	22
less Imports of goods and services	-6,983	-30
	-1,881	-8
Gross domestic product at current market prices	23,610	100

Source: *National Income and Expenditure*, 1961 (reprinted by permission of Her Majesty's Stationery Office, London).

As defined for the purposes of national accounting it should be stressed that the value of consumption excludes many items of private or potential exchange value produced by private individuals for their own use or for the use of members of their household. In an urban community perhaps the most important items are the domestic services of housewives; in rural communities, particularly in countries with poor communications and few developed markets, many items of food, clothing and domestic utensils are so produced and often evade evaluation. This limitation on the concept of consumption, enforced by the practical difficulties of objective measurement, is of no serious consequence in the comparison of consumption levels between two countries of similar social organization or over short periods of time in in-

dustrialized countries. But great difficulties arise when widely disparate economies are compared, or when a predominantly non-market economy embarks on a program of rapid industrialization. In such cases care must be taken to avoid too facile an identification of apparent consumption levels with the total enjoyment of goods and services, however produced, which might be taken as an indication of economic welfare.

**Distribution of Consumption.**—Table I shows that even in western countries a significant part of total consumption, and its allocation to particular goods and services, is determined directly by the expenditures of central and local governments. Some of the benefits of this part of consumption, such as defense expenditure or expenditure on public hygiene services, are widely diffused, but others are directed by common consent to the benefit of particular sections of the community. In part these provide specialized services, such as education or the medical care of the infirm or of expectant mothers; but others, such as the provision of assistance to the unemployed, of state pensions for old people and of assistance to children and wives deprived of the support of a family breadwinner, are designed to create greater equality in individual levels of consumption than would obtain under an unrestricted system of free enterprise. In normal times of peace the distribution of the nongovernmental share of consumption is almost entirely determined by the incomes of individual households and by the prices at which commodities are sold in the open markets. On the total level of demand for private consumption and on its allocation to particular goods and services, governments may and do operate in a number of ways in pursuance of a range of objectives. These objectives include the maintenance of a stable price level, the control of the demand for commodities imported from abroad, the avoidance of intolerable degrees of inequality and the discouragement of the excessive consumption of particular commodities that are considered harmful. The government's main instruments are the direct taxation of incomes and the indirect taxation of goods and services. Rationing of commodities is considered clumsy and inequitable in normal times, though necessary during periods of abnormal curtailment of supply when it is unreasonable to expect that the price mechanism alone will tend to bring production into line with the expressed preferences of the general public.

Many governments found it necessary after World War II to adopt various forms of control of consumer credit. An increasingly significant part of consumer demand has been directed since the war to the acquisition of large and more or less durable goods such as automobiles, refrigerators and other household appliances. Most consumers find it difficult to purchase such items at one stroke from current income or accumulated savings. Thus the provision of easy terms of purchase by which expenditure may be spread over one or two years into the future becomes of crucial importance in determining the level of current demand for these commodities. In some cases the imposition of restrictions on credit facilities is more effective in controlling consumption than the imposition of increased indirect taxes. (See also **INSTALLMENT CREDIT**.)

**Consumption as a Branch of Economics.**—The study of consumption as the final aim of economic activity has always been a major branch of economic science. In the 20th century three major developments have been added to it. First, the study of welfare economics, particularly by V. Pareto and A. C. Pigou, which attempts to construct criteria of an economy's progress based on consumption levels; second, the understanding of the importance of the desire for consumption in determining the short-run fluctuations and trend of a free-enterprise economy, so strongly associated with the name of J. M. (later Lord) Keynes; and third, the detailed study of the demand for particular commodities based on modern statistical techniques.

The beginning point in welfare economics has been the traditional assumption that the individual consumer uses his income to purchase commodities available to him at given market prices in such a way as to obtain the greatest possible satisfaction. This much is generally accepted by economic theorists and the refined expression of this theory is given by J. R. Hicks in *A Revision*

of *Demand Theory* (1956). But most economists are skeptical with regard to the attempt to pass from a measure of satisfaction of the individual to that of a community. The essential obstacle is that, as the result of some event or act of policy, the consumption of some individuals in the community may be increased while that of others is decreased; and there exists no conceptual means of deciding whether one man's gain outweighs another's loss. The state of controversy is well summarized by E. J. Mishan in "A Survey of Welfare Economics," *Economic Journal* (1960). Nevertheless, most economists acting as advisers or policy makers rather than as theoreticians would act on a presumption that a movement toward greater equality in consumption levels per se increases total welfare and is to be recommended in the absence of unwelcome secondary effects. This principle, so important still in international as well as national economies, was based originally on the contention that as consumption increases the marginal satisfaction obtained from it declines. Hence a given extra amount of consumption means more to a poor man than to a rich one, or more to a poor community than to a rich one. This is now, regretfully perhaps, rejected as a *non sequitur* by the theoreticians, but retains a hold on the minds of men in the hope that one day its human appeal may be enhanced by theory.

The importance of consumption expenditure in the Keynesian theory of employment derives from the fact that income so spent forms the revenue of enterprises which in turn pay out their receipts in the form of wages and profits. Income saved, on the other hand, does not necessarily give rise to demand for commodity production, since intentions to save and intentions to incur investment expenditure are made by different social groups from different motives. If at a time when some productive capacity is idle through lack of demand a new project is undertaken which involves the payment of factor incomes, the total national income is increased by more than this direct payment. A proportion of these incomes may be saved but the larger part will be spent on consumption goods. The total increase in consumption demand so induced may be two or three times the size of the initial expenditure, and the ratio of the former to the latter is known as the multiplier. The value of the multiplier is a characteristic of the economic environment in which it operates and depends directly on the typical proportion in which incomes are divided between saving and current consumption expenditures. This division is controlled by what Keynes, in *The General Theory of Employment, Interest and Money* (1936), termed the "propensity to consume" or its complement, the "propensity to save." In a typical mature economy of the 1930s, an increase in the propensity to save was likely to be damaging since the process described would operate in reverse and would result in a higher level of unemployment and more productive capacity lying idle. In addition to this carefully worked out short-run analysis Keynes's thought was tinged by a long-run pessimism. It was probable, he thought, that as countries grew richer their desire to acquire consumption goods would not expand proportionately with the growth in their incomes. This would lead toward stagnation and a chronic problem of unemployment both of men and machines.

These pessimistic forecasts were challenged first by Simon Kuznets who examined a long record of data of consumption and national income in the United States and concluded that there was no evidence that the proportion of income spent on consumption had declined even though incomes had risen considerably. This conclusion was later confirmed for other countries and is now generally accepted. Later writers, notably M. Friedman, J. S. Duesenberry and Franco Modigliani, have given varying theoretical reasons for this stability. All such theories are based on a distinction between the effects on consumption of short-term and long-term changes in income. All suggest that though sudden changes in the income of an individual do not lead to equal proportionate changes in his consumption expenditure, in the long run human wants will continue to expand as quickly as does the ability to satisfy them. The economic environment after World War II, with its prolonged boom in the demand for durable consumer goods, was almost uniformly favourable to these optimistic critics of the original Keynesian thesis, though

later experience in the United States and western Europe created some grounds for renewed doubt.

The empirical study of the factors influencing demand for particular goods and services has itself a long history. The work of Gregory King in this area antedates the emergence of economics as a general field of human study in the work of Adam Smith. Although the systematic collection of data on consumption progressed during the 18th and 19th centuries, the foundation of modern demand analysis was laid by Ernst Engel in his studies of family budgets. In the 20th century H. L. Moore, E. J. Working and H. Schulz were the first to make extensive studies of the influence of income and price changes on the demand for agricultural products. For the first time systematic analysis was made of chronological series of consumption, price and income data and the concept of elasticity of demand set forth by Alfred Marshall was subjected to the process of measurement. The classical approach to the study of the demand for food reached a high level of statistical refinement in the works of J. R. N. Stone and of H. Wold, published in the mid-1950s, the emphasis of whose analysis is placed on the importance of income and price as consumption determinants. Modern work centres more on the other categories of consumption expenditure, and on the interrelation between economic and other social and cultural factors influencing consumption habits. In most industrialized countries analysis of the kind described is supported to a varying extent by empirical market research, carried out by private industry or government agencies. In the past, effort has been centred mainly on short-run forecasts of market conditions, but there is an increasing tendency in both commercial market research and academic studies to aim at longer-run predictions. The purpose of this work is to guide investment programs.

**Data on Consumption Levels.**—The two major types of published consumption data are: (1) national estimates based on production and imports, and (2) estimates based directly on enquiry from private individuals, households or local distribution points. In the former case the information, arising often as a by-product of administration, is based usually on a complete enumeration of sources of supply, and allowance has to be made for stock changes, wastage and other factors before an estimate of final consumption is arrived at. In the latter case, because of the large number of consumers and distributive outlets, the information is usually taken from representative samples covering a small proportion of the population involved. National estimates, of the type used in national income accounting, are usually compiled annually, but may also be available at quarterly or monthly intervals. For commodities which are largely imported, or whose production is concentrated in well-defined industrial undertakings, annual statistics are usually reliable and complete, especially if the commodities are taxed and hence are subject to statistical control by the central government. But the consumption of commodities whose production is small-scale, local and independent of any easily checked raw material is often underestimated and fluctuations therein pass unmeasured.

Modern sampling techniques have raised the level of family budget inquiries from that of individual case studies to that of a relatively reliable and inexpensive method of collecting continuous information. The method further permits analysis of the aggregate estimates derived from the survey, since the data can be tabulated separately for different social groups, for different regions or according to any other classifiable characteristics. Thus in the United Kingdom such budget inquiries are used to get behind, as it were, the national aggregates of consumption obtainable from supply sources, to study the distribution of consumption and to estimate the influence of changing social factors; while in India the survey method is used primarily because of the difficulty of obtaining national estimates from any other source.

After World War II great progress was made by international agencies, such as the department for economic and social affairs of the United Nations, the International Labour organization (ILO), the Food and Agriculture Organization of the UN (FAO), the Organization for European Economic Cooperation (after 1960,

Organization for Economic Cooperation and Development [O.E.C.D.]) and the European Common Market (European Economic Community [E.E.C.]) in settling common definitions and methods of tabulation of consumption statistics. In particular the O.E.C.D. annually publishes comparable food consumption level estimates for its member countries. These are extended to most member countries of FAO, though the level of reliability varies considerably. Similarly, the O.E.C.D. publishes annual estimates of the national accounts of all its member countries corrected to a common basis of definition, in which consumption can be viewed against other relevant aggregates. The ILO has devoted a good deal of attention to international comparisons of consumption statistics. This work has aimed at achieving international agreement on a set of indexes covering the standard of nutrition, education (literacy) and medical care, as well as the more traditional indexes of consumption of commodities and services.

**Major Surveys of Consumption.**—The regular annual publication of comprehensive consumption statistics was begun in the United Kingdom during World War II. Since then the series has been extended back to 1920 by R. Stone, and the period from 1900 to 1919 has been covered by A. R. Prest. Similarly in the United States detailed estimates of consumption expenditures are available from 1909. In the United States the first extensive budget inquiry was carried out in 1935–36. From 1941 onward numerous budget surveys have been made by the National Resources Planning board, the federal reserve board, the bureau of labour statistics and the bureau of the census. In general, the emphasis of these inquiries has lain on the elucidation of factors influencing the total level of consumption, such as money income, liquid assets, savings, and plans and expectations concerning future incomes and expenditures.

In the United Kingdom the first large-scale household inquiry was conducted in 1937–38 in order to establish weights for the ministry of labour's cost of living index. Hence this survey was confined to the families of employed insured workers, which at that date comprised most manual workers and the lower grades of clerical workers. The technique was to collect records for expenditure covering four separate weeks (spaced at three-monthly intervals) from each household approached and willing to participate. In the successor to this survey after World War II, carried out in 1953–54 by the ministry of labour and published as *Report of an Enquiry into Household Expenditures, 1953–54*, each household kept a record for a continuous period of three weeks, and a moderate payment was made as an inducement to co-operate. This survey was repeated on a continuous basis after 1957, each household keeping a record for two consecutive weeks. (See also COST OF LIVING.)

The second major sampling inquiry carried out in the United Kingdom is known as the National Food survey and is carried out by the government's social survey organization on behalf of the ministry of agriculture, fisheries and food. The survey began as a continuous study of consumption by families of urban workers in 1942, and its primary objective was to watch the nation's nutrition for danger signs under wartime conditions. From 1951 it was reorganized to cover the whole population of Great Britain. Every year it samples about 10,000 households, each of which maintains a record of food purchased for a single week.

An inquiry on similar lines was carried out in France in 1956, covering the whole field of consumption expenditure. In a number of other continental European countries, notably the German Federal Republic, Poland and the U.S.S.R., the method preferred is to sample a smaller number of households who keep records for a longer period, namely a year or more. By these means it is hoped to avoid fluctuations in the estimates because of changes in composition of the sample. Against this view must be placed the disadvantage that the record-keeping households may become habituated, and their pattern of expenditure cease to be representative of the population at large.

Other major sampling inquiries are the National Sample survey of India, which has concentrated on differing objectives in a number of different phases, or rounds, and the continuous sample survey carried out by the office of the prime minister of Japan.

The Food and Agriculture organization had undertaken the collation of budget surveys covering the consumption of food, textiles and clothing carried out in member countries. Information and standardized tables relating to about 50 such surveys are given in its *Review of Food Consumption Surveys* (1959).

**National Consumption Levels and Trends.**—The distribution of private consumers' expenditure among the main categories of goods and services in the United Kingdom is shown in Table II for 1938, 1949 and 1959. The table shows that the distribution of consumption as well as the level of its total were similar in 1949 to those of the last year before World War II. In the ten years following 1949 there were substantial increases in most categories. By 1959, 54% of total consumption was accounted for by items of personal expenditure, namely food, drink, tobacco and clothing. A further 18% was spent on maintaining the household, not counting 3% spent on equipping it with radios and other electrical goods. Private and public transport and communications absorbed 10%, and the remaining 15% was divided roughly equally between other goods and services.

TABLE II.—*Private Consumers' Expenditure in the United Kingdom Valued at 1954 Market Prices*

Item	£000,000			Percentage increase of 1959 over 1949	Percentage distribution in 1959
	1938	1949	1959		
Food	3,264	3,464	4,180	21	30
Alcoholic drink and tobacco	1,569	1,555	1,881	21	14
Clothing and footwear	1,141	1,184	1,440	22	10
Housing services	832	935	1,080	15	8
Fuel and light	427	432	542	25	4
Furniture and household goods	680	617	827	34	6
Radio and electrical goods	126	159	427	168	3
Motor vehicles and running costs	154	182	782	330	6
Public transport and communications	358	515	536	4	4
Recreational goods and services	302	489	489	0	4
Other goods	650	347	463	34	3
Other services	1,258	1,061	1,100	4	8
Total	10,761	10,940	13,747	26	100

Source: *National Income and Expenditure* publications for various years (reprinted by permission of Her Majesty's Stationery Office, London).

In the ten years preceding 1959 most of these categories had expanded in rough proportion to the total, though the rates of increase for food, clothing and household goods may be higher than for a normal peacetime period because these items were most affected by rationing in 1949. On the other hand notable increases occurred in expenditure on radio and electrical goods of all kinds and on the acquisition and use of automobiles. The very small increases in expenditure on recreation and other services conceal actual declines in motion picture expenditure and payments for domestic service, because of increased use in the home of television and labour-saving electrical equipment.

The extent to which these changes in consumption patterns in the United Kingdom are typical of a wider range of countries may be seen from Table III. Thus most industrialized countries have shown a compound rate of increase of 2% to 3% per year during the 1950s, the main exceptions being Canada, which experienced high rates of immigration and foreign investment, and Italy, which grew rapidly from a low base.

TABLE III.—*Percentage Increases in the Volume of Private Consumption Over Ten Years*

Country	Food	Clothing	Rent	Durables	Other	Total
Denmark*	20	15	19	112	24	28

But the pattern of change is similar in all countries. The volume of consumption of food and clothing has increased less than the total, and that of the consumption of durable goods by very much more, except in the United States, which experienced these changes at an earlier date. Changes in rent expenditure reflect to a large extent the varying use of rent control and building policies by governments rather than the free choices of consumers.

Comparable data for non-European countries are much harder to obtain and usually less reliable. But it is safe to suggest that, expressed as a proportion of total consumption expenditure, food expenditure is roughly twice as important over large areas of Asia and Africa as it is in western Europe and North America. Thus family budget inquiries show (see Table IV) that in many countries with a disposable income per head of about U.S. \$100 per year, approximately two-thirds is spent on food, as compared with a proportion of about one-third spent for food by urban families in the United States and the United Kingdom.

The character of food consumption itself varies considerably from country to country. In part these variations are due to climatic factors and reflect long-established food habits. The Scandinavian diet is relatively poor in vegetables but contains a high proportion of milk, fats and sugar. On the other hand the consumption of vegetables and meat is high in France. In general fruit and vegetable consumption is high in southern Europe where milk consumption is low. In Italy, Greece and Turkey food grains are preferred to potatoes as sources of carbohydrates. But over and above these regional variations is evident the influence of variations in the living standards of the countries concerned.

TABLE V.—*The Income Elasticity of Food Expenditures in Rich and Poor Countries*

Food	U.S. 1955	U.K. 1958	Italy 1953	Japan 1955	India 1952
Bread and cereals	0.1	0.2	0.2	0.2	0.3
Sugar	0.3	0.1	0.9	—	1.1
Fruit and vegetables	0.4	0.7	0.8	0.6	—
Meat	0.3	0.3	1.1	—	1.3
Fish	0.2	0.4	0.9	—	1.5
Milk products	0.3	0.3	0.8	1.2	—
All food expenditure	0.3	0.3	0.7	0.6	0.8

Note: All elasticities are derived from analyses of the budgets of urban households.  
Source: Food and Agriculture Organization, *The State of Food and Agriculture* (1959).

Thus the diet of the United States and Canada, with low levels of grain and potato consumption, and high levels of consumption of sugar, meat, eggs and fats, is indicative more of a high standard of living than of regional peculiarities of taste. These tendencies may be observed in the diets of the wealthier classes in most countries. (See FOOD SUPPLY OF THE WORLD.)

Trends in consumption induced by increases in income are generally measured by economic statisticians in the form of income elasticities, defined as the percentage increase in consumption divided by the percentage increase in income assumed to generate it. These elasticities may be obtained for a given country by comparing the household budgets of the rich with those of the poor in the same country.

Table V shows that the income elasticity of most items of food expenditure in the United States and the United Kingdom is of the order of 0.3, though the figures for fruit and vegetables are somewhat higher, especially in the United Kingdom. In Italy, Japan

and India, on the other hand, the figures for animal products and sugar are of the order of 1.0 or more, reflecting the fact that better nutrition ranks high in the scale of priorities for households in these countries.

Consumption levels in rural areas of underdeveloped countries are extremely difficult to measure with accuracy, especially where the illiteracy rate is high and the population is not accustomed to rendering regular returns on its activities. But a number of surveys collected by the FAO from Central America, Africa and southeast Asia show consumption levels of about 2,000 calories per person per day in rural areas and low levels of consumption of proteins and important vitamins. The difficulty of raising these to the level of 3,000 calories per person per day typical of North America and western Europe is enhanced by the rapid rate of growth of population in many of these areas.

### CONSUMPTION: see TUBERCULOSIS.

**CONSUS**, an ancient Italian deity, cult partner of Ops. The time at which his festival was held (after harvest and seed sowing), the nature of its ceremonies and amusements, his altar at the end of the Circus Maximus always covered with earth except on such occasions, all point to his connection with agriculture. His name is clearly derived from *condere*, to store away, and he is in all probability god of the store bin.

Anciently, when the true meaning of his cult was forgotten, three explanations were rife: (1) he was a god of good counsel (according to Varro); (2) he was Neptunus Equester—i.e., Poseidon Hippios (according to Livy); (3) he was god of hidden or secret policy (Dionysius of Halicarnassus, *Roman Antiquities*).

Among the ancient writers Consus was most commonly iden-

tified with Neptunus Equester, and in later Latin poets Consus is used for Neptunus, but this idea was due to the horse and chariot race that took place at his festival; otherwise, the two deities have nothing in common.

According to another view, he was the god of good counsel who was said to have "advised" Romulus to carry off the Sabine women when they visited Rome for the first celebration of his festival (Consualia). In later times, with the introduction of Greek gods into the Roman theological system, Consus, who had never been the object of special reverence, sank to the level of a secondary deity whose character was rather abstract and intellectual.

His festival was celebrated on Aug. 21 and Dec. 15. On the former date, the *flamen Quirinalis* (see **FLAMEN**), assisted by the vestals, offered sacrifice, and the pontifices presided at horse and chariot races in the circus. Horses and mules, crowned with garlands, were given rest from work. A special feature of the games in the circus was chariot racing, in which mules took the place of horses. The origin of these games was generally attributed to Romulus, sometimes to Evander.

There was a sanctuary of Consus on the Aventine, dedicated by L. Papirius Cursor in 272 B.C.

**CONTANGO:** see **STOCK EXCHANGE**.

**CONTARINI**, a distinguished Venetian family, one of the 12 that elected the first doge in 697 and later gave Venice eight doges and many other eminent citizens.

The first of the family to be invested doge was Domenico, during whose reign (1043-70) Dalmatia was subjugated and the rebuilding of St. Mark's church was begun. Andrea, doge from 1368 to 1382, ended the war with Genoa by defeating its fleet at Chioggia; he was the first to melt down his plate and mortgage his property for the benefit of the state. Gasparo (1483-1542) was a cardinal and diplomatist; as papal legate to the diet of Regensburg (1541) he favoured certain concessions to the Protestants.

Seven Contarini fought at Lepanto. Marco Contarini (1631-89) was a celebrated patron of music whose collection of musical manuscripts is now at the Marciana library in Venice.

**CONTÉ, NICOLAS JACQUES** (1755-1805), French mechanical genius who took an important part in Napoleon's expedition to Egypt in 1798, was born at Aunou-sur-Orne near Sées on Aug. 4, 1755. At the age of 14 he displayed precocious artistic talent and took up portrait painting, from which he derived a considerable income. He then gave free rein to his passion for the mechanical arts and scientific studies, and events of the French Revolution soon gave him an opportunity to display his inventive faculty. The war with England deprived France of its supply of native graphite, then known as plumbago, from Cumberland; he substituted for it a mixture of graphite and clay the method on which the manufacture of all modern pencils is based. Summoned by Napoleon to take part as chief of the balloon corps in the expedition to Egypt, he considerably extended his field of activity. The disaster of Aboukir and the revolt of Cairo had caused the loss of the greater part of the instruments and munitions taken out by the French. Conté seemed to be everywhere at once and triumphed over apparently insurmountable difficulties. He made, in an almost uncivilized country, utensils, tools and machinery of every sort from simple windmills to stamps for minting coin. As a result of his activity and genius, the expedition was provided with bread, cloth, arms and munitions of war; the engineers with the exact tools of their trade; the surgeons with operating instruments. He made the designs, built the models, organized and supervised the manufacture, and seemed to be able to invent immediately anything required.

On his return to France in 1802 he was commissioned by the minister of the interior, Jean Chaptal, to superintend the publication of the great work of the commission on Egypt. An engraving machine of his construction materially shortened this task, which, however, he did not live to see finished. He died at Paris on Dec. 6, 1805.

**CONTEMPT (LEGAL).** The concept of contempt in Anglo-American law goes back to the 12th century and is based on the notion that any insult to the crown or interference with or

violation of its orders is properly subject to punishment. In modern times the concept is utilized in two major areas, contempt of court and contempt of the legislature, each of which is characterized by sufficiently different processes and problems to warrant separate treatment. Though the procedure which governs and regulates judicial and legislative contempt proceedings differs from jurisdiction to jurisdiction in many particulars, the description which follows, based principally on U.S. law, is typical in its broader aspects. Additional points of English law are included in a special section at the end of the article.

**Contempt of Court.**—Any act of disobedience of a lawful order of a court, or any act which interferes with the administration of the law by a court, falls into the category of contempt of court. The primary importance of the notion of contempt is that it warrants judicial action in defense of the judicial power itself and without many of the safeguards that generally restrict the power of the state in the punishment of actions specifically categorized as civil or criminal wrongs. For purposes of noting which of these safeguards are present and which are absent in such proceedings, it is necessary to categorize contempt proceedings into civil and criminal, direct and indirect.

An act or language which consists solely of an affront to the court or interferes with the conduct of its business quite clearly falls in the category of criminal contempt. An act of disobedience to a court order, however, because of its multiple effects, may properly be treated either as civil or criminal contempt or both. Certainly such disobedience is an insult to the court as well as an interference with its judicial authority, and therefore constitutes criminal contempt. The same act of disobedience, however, may have the consequence of depriving a party to a lawsuit of the relief which the court order afforded him. Insofar as the sanction or penalty is imposed because of the interference with judicial authority, the wrongful act is a criminal contempt. Insofar as the sanction or penalty is utilized for the purpose of securing to the litigant that to which he was entitled under the court order, or for the purpose of compensating him for the loss resulting from the disobedient act, the contempt is civil in nature. The strange doctrine which results is that the categorization of the contempt as civil or criminal depends not on the act itself but rather on the purpose for which the sanction is imposed.

In both criminal and civil contempt proceedings, but more commonly in the former, a distinction is drawn between contumacious acts which take place in the presence of the court and are labeled direct contempts and those which are committed outside the geographical boundaries of the court and are called indirect or constructive contempts.

**Civil Contempt.**—Where the contempt is civil, the invocation of the contempt power is only at the instance of the injured party. In order to compel compliance with an order, the court is authorized in civil contempt proceedings either: (1) to order the defendant in the contempt proceedings to reimburse the injured party for his loss; (2) to threaten the wrongdoer with sanctions unless compliance is forthcoming; or (3) to impose a fine or imprisonment of fixed amount or duration, or of indefinite amount or duration, i.e., a certain sum for each day of failure to comply or imprisonment until obedience to the order is forthcoming. It is possible to utilize a combination of these alternatives. It is commonly said that, under the last choice listed, the defendant "carries the keys to his own prison," since he can secure release by compliance. There is, indeed, no practical alternative limit on the term of imprisonment. In one Illinois case the contemner was kept in prison for nine years for failure to comply with a judicial order.

If the civil contempt is direct, the court is empowered to act summarily; i.e., to impose a sanction without holding a trial or taking evidence. If, as is more usual in civil contempts, the contumacious action is labeled constructive, the question raised by the charge will be heard by the court sitting without a jury, and the proceedings will be governed by the ordinary rules of civil procedure. There is no right to a jury trial in civil contempt proceedings, and congress, at least, has not commanded jury trial in any such proceedings.

Where the contempt proceeding is civil and it is determined after the issuance of the contempt order that the order which was violated and which gave rise to the sanction was an erroneous one, the defendant is entitled to relief from the sanction to the extent that relief is available.

**Criminal Contempt.**—Where the proceedings are for criminal contempt, they are initiated at the instance of the court and not by a party who may have been injured by the act, although that party may call the wrongdoing to the court's attention. The available sanctions are imprisonment for a fixed term or a fine in a fixed amount, but not, under federal legislation, both. Except in a few special instances, there is no limit on the period of incarceration or the amount of the fine—which may be repeated each time the offense occurs—except for the power of an appellate court to limit the action of the trial judge as an abuse of discretion. Sentences for as long as four years have been imposed. In the case of *U.S. v. United Mine Workers*, 330 U.S. 258 (1947), the fine imposed by the district court was \$3,500,000, which was reduced to \$700,000 by the U.S. supreme court on condition of compliance with the order.

In the event of direct criminal contempt, as with direct civil contempt, the court may act summarily without taking evidence or providing for a trial. Where the contempt is indirect, a trial governed by the usual rules of criminal procedure, including the necessity for proof of guilt beyond a reasonable doubt, is utilized. There is, however, no constitutional right to a jury trial in criminal contempt proceedings whether direct or indirect contempt is involved. But congress has created a right to jury trial in three classes of cases: (1) where the contumacious act also constitutes a crime under state or federal law; (2) where the wrongful act consists of disobedience to an injunction issued in a case involving a labour dispute (an exception not applicable where the United States is the employer); and (3) where the contempt is a violation of an order issued pursuant to the Civil Rights act of 1957.

For many years it was believed that the contempt power was not subject to legislative control in any way and that it was, therefore, beyond the power of congress to authorize jury trials in contempt cases. This belief, however, was proved to be based on a historical error, and the congressional power, at least in the area of indirect criminal contempts, has been sustained.

Unlike the rule applicable to civil contempts, an erroneous order, unless palpably beyond the jurisdiction of the court, will not relieve the contemner of the obligation to obey it. Thus, a fine imposed for disobedience of an order will not be remitted even though the order was erroneously issued in the first place. This rule, established by the *United Mine Workers* case, has been the subject of much criticism.

Since the same act may constitute both civil and criminal contempt, a single proceeding may be used to resolve the questions raised by each, as long as the protections that are afforded a defendant in criminal contempt proceedings are observed. Under such circumstances, however, it is incumbent on the court to distinguish the sanctions imposed for criminal contempt from those imposed for civil contempt.

It is obvious that the power of punishment for contempt of court is subject to great abuses. The very judge whose order was disobeyed or whose authority is flouted is the judge who sits in judgment and imposes sanctions on the contemner. In cases of summary proceedings, there is not even the opportunity to present evidence. The U.S. supreme court has ruled, however, that at least in cases of criminal contempt, where it is not regarded as necessary to impose sanctions immediately, the offended judge should disqualify himself from presiding at the later contempt proceeding. The same considerations would seem to disqualify the judge in any case of nonsummary procedure. But the courts have not so ruled.

**Contempt of Court by Publication.**—One major difference between the U.S. and English doctrines of contempt of court is to be found in the treatment of newspaper and periodical comment on pending judicial proceedings. The English courts have been stringent in applying contempt sanctions against all commen-

tary on pending judicial business except for fair and accurate report of the proceedings themselves. The U.S. courts have resolved the conflict between the assurance of a fair and impartial trial and notions of freedom of the press in favour of the latter. According to U.S. doctrine, no publication can be restrained or serve as the basis for a charge of contempt unless it is clearly established that the newspaper comment presents the immediate danger of disorderly or grossly unfair administration of justice. The result in the United States has been unrestricted "trial by newspaper," a practice which has frequently deprived defendants of the right to a fair trial, particularly in notorious cases. There is developing, however, a doctrine calling for the reversal of a conviction where the abuse may be shown to have deprived the defendant of a fair trial.

**Contempt of the Legislature.**—The power of the houses of parliament, like that of the law courts, to protect the integrity of their own processes has a long history. Both houses have exerted the power summarily to punish such contumacious acts as infringement of parliamentary privilege, assumption of parliamentary functions such as the power to decide disputed elections, or insult to or libel of its members. The power to punish for contempt has involved the sanction of direct imprisonment of the offender by the offended house. The house of commons, however, can detain an offender only during its session, while the house of lords can detain for any fixed period, extending even beyond adjournment.

According to English doctrine, the legislative contempt power belonged solely to the "mother of parliaments" and did not extend to the legislatures of the colonies or commonwealth nations unless specifically granted by parliament. And the supreme court of the United States has announced, if on erroneous grounds, that congressional power in this area is not derived from the English precedents. Nonetheless, both the national and state legislatures have exercised these powers almost from the start. U.S. supreme court sanction of the power of congress in this regard was forthcoming as early as 1821, when the court sustained the warrant of arrest issued by the speaker of the house of representatives pursuant to the exercise of its contempt power. But the doctrine that incarceration for legislative contempt could not last beyond the end of the legislative session, among other problems, led congress to turn the courts into enforcement agencies. In 1857 the first of a series of statutes relating to contempt was passed. It authorized criminal prosecution for those who interfered with congress' investigatory powers and provided for a fine and a prison term of up to one year for those found guilty of such contempt. Congress, nevertheless, has also continued to exercise its own power to imprison for contempt.

As the 1857 statute would indicate, the most important use of the legislative contempt power has been, and continues to be, to compel testimony before its investigating committees. And it is in this area that the problems have been presented to the courts. In *Kilbourn v. Thompson*, 103 U.S. 168, 189 (1880), the supreme court held that the congressional investigating powers were subject to constitutional limitation and therefore to judicial review. It there sustained a witness' suit for false imprisonment against the sergeant at arms, on the ground that the inquiry directed to him was beyond the scope of congressional authority. And, in 1917, the supreme court held that it was beyond the contempt power to punish the writer of a defamatory and insulting letter about the activities of a congressional committee, because the object of the contempt power is "self-preservation" and not punishment, and its exercise, therefore, must be limited to "the least possible power adequate to the end proposed" (*Marshall v. Gordon*, 243 U.S. 521, 541 [1917]). The *Kilbourn* case and *Marshall v. Gordon* represented the high watermark of judicial limitation of the congressional investigating power. The tide began to recede in 1927, when the court held that the legislature had the power to compel the testimony of Atty. Gen. Harry M. Daugherty's brother in an investigation of the conduct of the department of justice. And the investigatory powers were again sustained in 1929 when a committee looking into the Teapot Dome scandal caused the indictment and successful prosecution of Harry Sinclair for violation of the 1857 statute for failure to testify.

Concurrent with the expansion of the power of the national government during the 1930s was the expansion of the congressional investigatory powers, since they could be used for any legitimate legislative inquiry. And the broad use of these powers by committee chairmen such as Senators Robert M. La Follette, Jr., and Hugo Black foreshadowed the even more controversial practices of the next decades.

The appropriate doctrines of limitation of the congressional investigative power on which the contempt power is based are easier to state than to apply. There is no doubt that a congressional committee can compel the attendance of witnesses. A witness who has refused to testify or to answer a question, however, cannot be held in contempt unless it has been made clear to him that his refusal will be treated as contumacious. The contempt must be deliberate and intentional, and the question addressed to the witness must be pertinent to the inquiry authorized by congress. Moreover, its pertinency must be made clear to the objecting witness. In order to accomplish the necessary showing of pertinency, the authorizing resolution must be sufficiently clear to inform the witness of the appropriate scope of the committee's authority. Also, the protection of the fifth amendment against compulsory self-incrimination applies to witnesses before congressional committees. (P. B. K.)

**English Law.**—Though the general principles underlying the law of contempt in England are the same as those outlined above in relation to the United States, it is important to bear in mind the distinction in English law between the superior and the inferior courts. The former have an inherent jurisdiction to protect their proceedings and to enforce their orders, as well as to protect inferior courts by the same means and subject to the same rules as they protect themselves. Inferior courts, it seems (although in relation to magistrates' courts it is not wholly free from doubt), have only such powers to protect themselves as are vested in them by statute. Thus, for example, by virtue of s. 157 of the County Courts act, 1959, a county court judge may order into custody and make an order either committing to prison for a specified period not exceeding one month, or imposing a fine of not more than £20 upon, any person who, for example, either willfully insults the judge or willfully interrupts the proceedings of a county court.

The Administration of Justice act, 1960, had an important effect upon the law of contempt. Section 11, altering the law as laid down in previous cases, made innocent publication or distribution of matter calculated to interfere with the course of justice a defense; s. 12 provided that publication or information relating to legal proceedings in private shall not of itself be contempt of court except in certain specified cases relating to such matters as infants, mental patients, national security and secret processes, and where the court expressly prohibits the publication of information. Section 13 provides, for the first time, for a right of appeal against orders or decisions of a court imposing penalties for contempt of court, such appeals lying to a divisional court of the high court, to the court of appeal or to the house of lords, according to the court that made the order from which the appeal is made.

There are, in English law, some questions of special difficulty in relation to the powers of each house of parliament to commit for contempt. In the somewhat unlikely event of a conflict between parliament and the courts on these matters, there would arise some fundamental difficulties of constitutional principle. (W. T. Ws.)

**CONTI, PRINCES DE**, a line of French princes belonging to the Condé branch of the house of Bourbon (see CONDÉ, PRINCES DE). The small property of Conti, in Picardy, passed to Louis I de Condé through his marriage with Éléonore de Roye.

The first prince to bear the name was FRANÇOIS DE BOURBON (1558–1614), a younger son of Louis I de Condé. He gave some valuable support to Henry of Navarre (Henry IV of France) in the civil wars, but was precluded from political distinction by a stammer which made him almost speechless. Married first, in 1582, to Jeanne de Coesme (d. 1601), then, in 1605, to Louise Marguerite de Lorraine (1574–1631), daughter of Henry, duc de

Guisse, he died in Paris on Aug. 13, 1614. His widow had enjoyed court life under Henry IV. Her novel *Adventures de la cour de Perse* (1629) reflects her youthful memories. She is also commonly credited with the better-known *Histoire des amours du grand Alcandre*, a satire on Henry IV's love life. Later she was secretly married to François de Bassompierre (q.v.), on whose arrest she was exiled from court. She died at Eu on April 30, 1631.

The next prince de Conti was ARMAND DE BOURBON (1629–1666), the second son of Henry II de Condé. Born in Paris on Oct. 11, 1629, the younger brother of the Great Condé and of the duchesse de Longueville (q.v.), he was despised by his brother because of his deformity and so fell entirely under his sister's influence. Destined for the church, he was the French crown's immediate nominee for a cardinal's hat; this gave rise to intrigues aimed at securing the nomination for another candidate if he should renounce it. On the outbreak of the Fronde (q.v.) in 1649, when his brother was supporting the government, his sister took Conti to join the Parisians, whereupon he was made generalissimo of the Fronde—to be the puppet of his supporters. Arrested with Condé and his sister's husband in 1650, he was released with them in 1651 as a result of the coalition between their faction and the Frondeurs, one of the terms of which was that he should marry Charlotte de Lorraine, daughter of the duchesse de Chevreuse (q.v.). He accordingly renounced his ecclesiastical prospects, but the bargain was set aside by Condé. In 1652 he was left by Condé in command in Bordeaux, whence government forces expelled him in July 1653. He then made his peace with Cardinal Mazarin, marrying his niece Anne-Marie Martinozzi (1637–72) in 1654 and being sent to command in Catalonia (1654) and in Italy (1657). After figuring as a patron of literature he fell like his sister under the influence of Jansenism. He died at Pézenas in Languedoc, of which he was governor, on Feb. 21, 1666. Some writings of his Jansenist period can be read in English translation, *The Works of Armand de Bourbon, Prince of Conti* (1711).

LOUIS ARMAND I DE BOURBON (1661–1685), prince de Conti, was Armand's elder surviving son, born in Paris on April 4, 1661. His marriage (1680) to Marie Anne de Bourbon (1666–1739), daughter of Louis XIV and Louise de La Vallière, was the first union between a prince of the blood and one of the king's bastards. On his return from Hungary with his brother (1685; see below), he died of smallpox at Fontainebleau on Nov. 9, 1685.

FRANÇOIS LOUIS DE BOURBON (1664–1709), called *le Grand Conti*, was born in Paris on April 30, 1664. Before succeeding his brother Louis Armand I as prince de Conti he was known as prince de la Roche-sur-Yon. In 1685 he and his brother, with other nobles, went to Hungary to serve in the Holy Roman emperor's army against the Turks. Louis XIV had first granted permission for this, then withdrawn it. On returning to France, Conti secured the king's formal pardon in 1686 thanks to the intercession of the Great Condé, whose granddaughter Marie Thérèse (1666–1732) he was to marry in 1688. Louis XIV, however, never forgot Hungary and long refused to let Conti command an army, though he did well in every campaign from 1688 to 1695, especially those under his friend the marshal duc de Luxembourg (q.v.). The king's dislike, moreover, was exacerbated as the well-informed, deliberately charming and sexually ambivalent Conti won prestige at court and ingratiated himself with the dauphin. To get rid of him, the king sponsored his candidature for the Polish crown, and Conti was elected king of Poland on June 27, 1697. Escorted to Gdansk by Jean Bart in September, he found the Poles converted to his rival Augustus II and he sailed back to France. In 1698 he won a law suit over the inheritance of the house of Longueville, but in 1699 he failed to establish himself as prince of Neuchâtel, to which the inheritance gave him some claim. His avidity for Neuchâtel was contrasted with his lukewarmness about Poland, where he would have been far from his French amours. Promised (1708) the supreme command in Italy, he died in Paris on Feb. 22, 1709.

LOUIS ARMAND II DE BOURBON (1695–1727), prince de Conti, was the only surviving son of François Louis. Born in Paris on

Nov. 10, 1695, he was married in 1713 to Louise Elisabeth (1693–1775), daughter of the duc de Bourbon (Louis III de Condé). Her infidelities were excusable, his were accompanied by horrifying depravity. He died in Paris on May 4, 1727.

LOUIS FRANÇOIS DE BOURBON (1717–1776), prince de Conti, was born in Paris on Aug. 13, 1717, Louis Armand II's second son. Married in 1732 to Louise Diane d'Orléans (1716–36), he campaigned in Germany during the War of the Polish Succession (1733–38) and in Bohemia (1742), in Piedmont (where in joint command of the Franco-Spanish forces he took Villafranca and besieged Cuneo in 1744), on the Rhine (1745) and in the Netherlands (1746) during the War of the Austrian Succession. Leaving the army because of a quarrel with the marshal de Saxe, he became in 1747 a confidant of Louis XV's secret diplomacy, much of which was directed toward winning Conti's election as king of Poland. In 1757, however, his disrespect toward Mme de Pompadour lost him the king's favour, and he had to withdraw to his estate at L'Isle-Adam. When Louis XV and the chancellor Maupeou (q.v.) began their attack on the *parlement* of Paris (1770–71), the traditionalist Conti led the opposition, remaining irreconcilable with the court when the other princes made their peace. Hostile also to Turgot's innovations, he was suspected of having instigated the bread riots of 1775, which spread to Paris from Pontoise (near his estate). However, he was a patron of J. J. Rousseau and Beaumarchais. He died in Paris on Aug. 2, 1776, leaving several illegitimate children.

LOUIS FRANÇOIS JOSEPH DE BOURBON (1734–1814), prince de Conti, only legitimate son of Louis François, was born in Paris on Sept. 1, 1734, and married Maria Fortunata d'Este (1731–1803) in 1759. After some military experience in the Seven Years' War, he made his name as a timeserver. Subservient to Louis XV's mistresses, a supporter of Maupeou and an opponent of the reforms suggested in 1788, he emigrated at the outbreak of the Revolution but returned to France in 1790. Found guiltless by the Revolutionary tribunal in 1793 and pensioned by the Thermidorians, he was banished from France in 1797. He died in Barcelona on March 10, 1814. (J. G. R.-S.)

CONTI, NICCOLO DE' (c. 1395–1469), Venetian merchant and traveler in southern Asia, was born c. 1395, possibly at Chioggia. As a young man he lived in Damascus, where he learned Arabic, and whence, in 1414, he set out for Baghdad. He next visited Basra and Ormuz before sailing along the Persian coast to the great emporium of Calacatia, where he learned the language, adopted native dress and entered into partnership with some Persian merchants who accompanied him to India and the East Indies. He visited Cambay, Vijayanaga and Maliapur. He referred next to Ceylon. His travels then seem to have taken him to Sumatra and thence, by way of Tenasserim, to Bengal, visiting Burdwan and Aracan before crossing over into Burma. He sailed down the Irrawaddy and visited Ava and Pegu. He then set out for Java, his farthest point. In due course he returned to Coloén (Kulam or Quilon) in the extreme southwest of India by way of Ciampa (usually Cochin China in later medieval European literature but here perhaps Thailand). Thereafter he continued his way back to Europe, visiting Cochin, Calicut, Cambay, Sokotra, Aden and Jidda. He then traveled overland to Cairo and reached Venice in 1444, where he seems to have traded until his death in 1469.

As penance for his renunciation of the Christian faith during his travels, Pope Eugenius IV ordered him to tell his story to Poggio Bracciolini, the papal secretary. His narrative, as well as his answers to Poggio's questioning on Indian life, religion, customs and other matters, throws light on the human geography of southern Asia in the 15th century.

The original Latin text is in Poggio Bracciolini's *De Varietate fortunae, libri quatuor*, 1447 (ed. by Abbé Oliva, Paris, 1723); Eng. trans. by J. Winter Jones in R. H. Major (ed.), *India in the Fifteenth Century*, Hakluyt Society (1857).

See also C. Bullo, *La vera patria di N. de' Conti* (1880); V. Bellemo, *I viaggi di N. de' Conti* (1883); M. Longhena, *Viaggi in Persia, India e Giava di N. de' Conti* (1929). (E. M. J. C.)

CONTINENT, one of the larger continuous masses of land, namely: Asia, Africa, North America, South America, Antarctica,

Europe and Australia, listed in order of size. The accompanying table indicates that there is great variation in the sizes of continents, the largest, Asia, being more than five times as large as Australia. However, the largest island in the world, Greenland, is only about one fourth the size of Australia. All the continents are completely separated discrete land areas, or nearly so, with the exception of Europe and Asia, which exhibit no clear dividing line. Europe, physically, is a number of peninsulas extending west from Asia, and the two areas are commonly referred to as the single continent of Eurasia.

*Size of Continents*  
(in 100,000 sq. mi.)

Continent	Area
Asia . . . . .	27.1
Africa . . . . .	11.8
North America . . . . .	8.5
South America . . . . .	6.9
Antarctica . . . . .	6.0
Europe . . . . .	4.0
Australia . . . . .	3.0

The earth's surface, in general terms, has two levels, the lower being at an average depth of three miles below the rest of the crust. The lower level, constituting the ocean basins, occupies by far the larger part of the total surface area of the earth—about 70%. Nearly all of the other, higher surface rises above sea level and constitutes the continents, although the continental margins are shallowly submerged and are referred to as the continental shelf (*q.v.*). The continents however, are not distributed even approximately evenly over the surface of the globe. If a hemisphere map centred in northwestern Europe is drawn, most of the world's land area can be seen to lie within that hemisphere; that is, on the opposite side of the globe from the water areas, mainly the Pacific ocean. More than two thirds of the earth's land surface lies north of the equator, and all the continents except Antarctica are wedge-shaped, wider in the north than they are in the south.

The polar areas exhibit exactly opposite conditions. The antarctic continent lies directly over the south pole and is surrounded by ocean; the north pole lies in the Arctic ocean, which is almost completely surrounded by North America, Greenland and Eurasia.

The continents differ sharply in their degree of compactness. Africa is the most compact, with the most regular coast line, and consequently has the lowest ratio of coast line to total area of any of the continents. Europe, if regarded as a continent, is the most irregular and indented and has by far the highest ratio of coast line to total area.

The distribution of the continental platforms and ocean basins on the surface of the globe and the distribution of the major land form features over each continent and ocean basin have long been among the most intriguing problems for scientific investigation and theorizing. The fields of geology, physics, physical geography, geotectonics, geodesy, astronomy and mathematics have all furnished data and ideas toward the various solutions of the problems. These problems of the origin and distribution of the largest earth features are still among the most highly theoretical and speculative in all of geophysics and physical geography. Changes in ideas and theories have come about partly from the accumulation of traditional data and partly through increased understanding of the physical processes taking place in the earth's crust.

**Early Theories of Continental Origins.**—One of the earliest scientific hypotheses that offered an explanation for both the arrangement and shape of the continents was the tetrahedral theory of Lowthian Green. Green assumed that the earth is cooling. The outer surface, being relatively cool, was not cooling further, but the inside, which was continuing to cool, was shrinking and thus no longer supporting the outer crust, which would then collapse under the force of gravity. Both theoretical and experimental data caused Green to conclude that the collapsing sphere would tend to develop a tetrahedral form, with the points of the tetrahedron rising above the oceans and the tetrahedron faces forming the ocean basins. This theory is now largely discredited, primarily on grounds of theoretical physics.

Eduard Suess (*q.v.*; 1831–1914) made significant advances over earlier theories when he put forth a hypothesis based on an interpretation of a large mass of observational data concerning the earth's surface. Suess showed that on every continent there were very old sedimentary rocks deposited in the sea in a horizontal position, which still maintained a horizontal attitude. Because they had been undeformed throughout much of geologic history it was clear that those parts of the continental surfaces were rigid and resistant. Between these rigid platforms, in contrast, the surface rocks had been repeatedly buckled, folded and crushed. Suess's theories were far more complex than this brief explanation indicates, but basically he tried to account for most of the earth's features in the general terms just described. For example, the great array of mountains scattered from Spain to China in a roughly east-west orientation he believed to have been crushed between the rigid platforms of the northern and southern hemispheres.

Alfred Wegener (1880–1930) introduced a theory, commonly known as the theory of continental drift, which was so striking and unusual that it attracted world-wide attention, caused scores of scientific papers to be written attacking or defending it, and still has many staunch and convinced adherents despite numerous grave theoretical difficulties. It had long been known that the continental portions of the earth's crust consist chiefly of the lighter and more acid rocks; beneath this, it was commonly supposed, there was a layer of denser and more basic rocks. Wegener essentially proposed that the light continents are floating on the denser underlying material. For a large part of geological history there was but a single land mass which covered about one third of the globe. About 200,000,000 years ago this single land mass broke apart; North and South America floated west and Eurasia and Australia drifted east. One of Wegener's chief arguments was an assertion that eastern North and South America would fit well into the outlines of western Africa and Europe.

John Joly (1857–1933) presented a theory based on the process of convection. He proposed that heat was generated in the interior of the earth by decay of radioactive elements. Since the heat could not escape sufficiently rapidly by other means, it started convection currents which carried hot material toward the surface where it cooled and sank, thus setting up a convective cell circulation. He suggested that the earth's crust was dragged sideways at the top of the cell, which caused buckling and folding and thus mountain making, and the crust collapsed above the sinking portion of the convection cell. The greatest difficulty with this theory is a complete lack of observational data indicating any convection currents or cells.

**Current Views on the Origin of the Continents.**—All early theories concerning the origin of the continents suffered from deficiencies of observational data concerning the topography of the ocean basins and the interior of the earth. Most of the earth's crust (70%) lies beneath the ocean, and very little was known about the topography of the ocean basins because soundings were so extremely expensive and difficult to make before the invention of sonic and electronic sounding equipment. It was not until the 1920s that information concerning the topography of the ocean basins began to accumulate rapidly.

Furthermore, all theories of continental origin are based on knowledge of or theories concerning the nature of the earth's crust and interior. The earth's interior cannot be observed directly. Most of what is known is derived from studies of the behaviour and characteristics of earthquake waves as recorded by seismographs, and it was not until well into the 20th century that world-wide seismograph records were systematically collected and reported.

Geological and seismological evidence both indicate that Wegener's view of the composition of the earth's crust was accurate. Underlying the continents is a layer, approximately 10 to 15 mi thick, of light-weight rock which is now called sial (Suess called it sal). The sial forming each of the continental platforms may be thought of as resting or floating on a crust of heavier, darker, crystalline material called sima (the original name proposed by Suess), which forms a layer completely enveloping the earth. The

sima layer extends down to an average depth of perhaps 20 mi. Beneath the ocean basins the sima layer (which is largely basalt) is at the surface, but beneath the continents it is severely depressed by the overlying sial that constitutes the continental platforms. The relationships are shown in the accompanying figure.

Two major features of the earth's topography, the earthquake and volcanic zones, have long been known. The high, rugged, youthful mountains of the world are arranged in two relatively narrow bands. The longer of the two bands borders the Pacific ocean and stretches in a long line from the southern tip of South America along the west coast of that continent, through Central America, along the west coast of North America through Alaska, Japan, the Philippines, and down into Indonesia.

When seismologists learned to locate and plot the origins of the several hundred major earthquakes that occur in the course of a year, they discovered that the overwhelming preponderance of them, about 95%, took place along these narrow bands of mountains. Likewise, many of the world's active volcanoes are located along these same narrow zones, and consequently much of the lava that reaches the earth's surface is being deposited there. (See also EARTHQUAKE; VOLCANO.)

Many earth scientists believe that such active zones of crustal breaks, volcanic activity, lava and ash deposition, and mountain building have been characteristic of parts of the earth surface throughout all of earth history that is visible in existing rocks. The ocean basins were established relatively early in earth history and have remained basins and, thus, constantly under water since that time. The very ancient continental platforms that have remained relatively stable for hundreds of millions of years were not always so quiet. The rocks that compose them are clearly associated with volcanic activity, and subsequently they were areas of profound crustal movement. Only thereafter did they become quiet and stable.

Each continent has one of these old so-called shield areas which formed from 2,000,000,000 to 4,000,000,000 years ago and is the core of the continent to which the remainder (most of the continent) has been added. In North America the whole northeast quarter of the continent, called the Canadian shield or Laurentian shield, and extending into Baffin Land and Greenland, is characterized by the ancient rocks of what might be called the original continent. In Europe, the shield area underlies the eastern Scandinavian peninsula and Finland. The Guiana highlands of South America are the core of that continent. Much of eastern Siberia is underlain by these ancient rocks, as are western Australia and southern Africa. (See also PRECAMBRIAN TIME.)

Adjacent to the areas of active mountain building on their seaward sides are huge deep troughs technically called geosynclines. These tremendous trenches are the deepest parts of the oceans. The young, high, actively growing mountains are subject to very active erosion, and the huge quantities of erosion debris are eventually deposited in the adjacent geosynclines. The added weight of this debris in the syncline is thought to depress the earth's crust at that point, with the result that the syncline can receive more sediment. Geological evidence indicates that this process continues for a long time, and enormous thicknesses of sediments accumulate.

After periods of time measured in hundreds of millions of years these geosynclines are lifted above the level of the sea and folded into major mountain ranges—the Sierra Nevada, parts of the Andes and the Himalayas. An enormous episode of this kind is called by geologists a revolution.

In fact, all major mountain chains are produced by the deformation of materials in a geosyncline. After this takes place the zone of fracture and active volcanic mountain building moves seaward. Why this happens or what causes it is one of the major unsolved problems of earth history.

As knowledge accumulates it becomes clear that even the rocks of the extremely old shield areas are older in the centre and younger toward the margins, indicating that this migration process started early. In North America the area of the Appalachian mountains was once a double syncline which was later folded into a

chain of mighty mountains and has since been worn down to a rather low mountain chain. The centre of the continent remained stable and was only shallowly submerged and never seriously warped or deformed. Simultaneously the Rocky mountain area became a series of synclines and in a revolution was transformed to a mountain mass; still later the Sierra Nevada-Cascade mountain region had a similar history. Thereby the continent has grown by accretion and by migration of the zone of fracture. The other continents have grown in a similar fashion.

The Kunlun mountains, the Himalayas and the Tibetan plateau of Asia are a recently deformed geosyncline, as is the Iranian plateau with its bordering range.

Thus the tremendous increase in observational data concerning the structure of the earth's crust and the arrangement of features on the continents has largely destroyed the all-embracing theories of the origin of continents, but has given increasing insight into the processes whereby the continents have grown and assumed their present shape and topographic features.

**CONTINENTAL CONGRESS, THE**, was the body of delegates who spoke and acted for the people of the colony-states of America collectively during the years 1774–89. It was never truly "continental," since large parts of British North America were not represented in it. The adjective is much more commonly applied to the congresses of 1774 and 1775–76, which are generally designated the first continental and second continental congresses, than to the later congresses.

The first continental congress met in Carpenters' hall, Philadelphia, Pa., on Sept. 5, 1774. The passage by the British parliament earlier in that year of the Coercive (or Intolerable) acts, including the closing of the port of Boston and measures to buttress royal authority in Massachusetts, provoked keen resentment in all the colonies. As early as May 27 the members of the Virginia house of burgesses in unofficial session urged that they present a common front and join in forming a congress. In June the lower house of the Massachusetts assembly issued a call, and all of the colonies except Georgia responded by sending deputies to Philadelphia.

The delegates were not chosen with any particular rule as to number. When the congress assembled there were 44 members, originating as follows: 2 each from New Hampshire and Rhode Island; 3 each from Connecticut, Delaware and Maryland; 4 from Massachusetts; 5 each from New York, New Jersey and South Carolina; and 6 each from Virginia and Pennsylvania. Three delegates arrived later from North Carolina, and when all late comers had reported, the delegates numbered 56. (Georgia did not participate until 1775 during the second congress.) Each delegation had been commissioned by its colony but the credentials furnished were of various sorts. Those for Rhode Island carried the governor's signature, those for Massachusetts, the clerk's; others offered as their credentials the vote of their assemblies. Methods of election varied as well, including election by provincial congresses (Maryland, New Jersey, Delaware, North Carolina), by deputies appointed by the several towns (New Hampshire) and by "a general meeting of the inhabitants," later ratified by the assembly (South Carolina).

Peyton Randolph of Virginia was unanimously chosen president of the congress, and the historic choice of the terms president and congress, for the chairman and the assemblage, were also made at this time. Charles Thomson of Pennsylvania was elected secretary and served in this office during the 15 years that the congress functioned.

The manner of voting was an early subject of debate, with Patrick Henry urging that the delegation from each colony be given

weight in accordance with population. However, spokesmen for the smaller colonies insisted that each colony have one vote, and it was necessary to meet their wishes in order to secure unity.

The first continental congress contained several great and many talented men, including Patrick Henry, George Washington, John and Samuel Adams, John Jay and John Dickinson. Meeting in secret session, the delegates rejected a plan offered by Joseph Galloway (*q.v.*) of Pennsylvania that attempted to reconcile British authority and colonial freedom. Instead, on Oct. 14, the deputies adopted a declaration of personal rights, including those of life, liberty, property, assembly and trial by jury. The declaration also denounced taxation without representation and the maintenance of the British army in the colonies without their consent. However, the congress announced cheerful acceptance of parliamentary regulation of American commerce.

The first continental congress, in addition, sent a petition to the king, adopted on Oct. 26, and an address to the British people. It did not petition parliament. In effect, it demanded of Great Britain redress of grievances accumulated since 1763, and in general a return to the relationship (as the colonists conceived it) that had existed between the mother country and the colonies in that year. Toward forcing Britain to comply, the congress, on Oct. 20, called for the formation of an Association of the colonies to bring economic pressure upon the mother country. The Association provided for nonimportation and nonconsumption of British goods after Dec. 1, 1774, and for nonexportation of American products, except rice, to Britain or the British West Indies after Sept. 10, 1775. It was to be enforced by local committees. Adjourning on Oct. 26, the delegates issued a call for a second congress, to meet on May 10, 1775, and to consider further steps in the light of the behaviour of the British government during the interim.

Before the second continental congress assembled in the Pennsylvania statehouse, hostilities began at Lexington and Concord, Mass. The membership of the new body was much like that of the earlier one but it included Benjamin Franklin and, later, Thomas Jefferson. Peyton Randolph was again elected as president but later withdrew and was replaced by John Hancock. The second continental congress "adopted" the New England forces that had converged upon Boston after the battles of Lexington and Concord, and appointed Washington commander in chief of the American army on June 15, 1775. Assuming general direction of the American war effort, it also acted as the provisional government of the 13 colony-states, issuing and borrowing money, setting up a postal service and creating a navy (*see AMERICAN REVOLUTION*).

Although the congress continued for some months to claim that the Americans were struggling for their rights within the British empire, it gradually cut tie after tie with Britain and encouraged the establishment of revolutionary governments in the several colonies. The continued clash of arms, the failure of Britain to offer satisfactory concessions, the employment by Britain of Hessian troops, a desire for French aid and other circumstances impelled the congress toward complete separation. On July 2, 1776, with New York abstaining, it "unanimously" resolved that "these United Colonies are, and of right ought to be, free and independent states." Two days later it solemnly approved the Declaration of Independence (*q.v.*) which explained why the congress had taken the decisive step of July 2.

The congress continued to direct the American war effort. It prepared the Articles of Confederation, which, after being sanctioned by all the states, became the first constitution of the United States in March 1781; and it continued to function under that constitution until 1789, when it was replaced by the congress under the constitution adopted in 1788.

Sessions of the continental congresses were begun as follows: Sept. 5, 1774, and May 10, 1775, at Philadelphia; Dec. 20, 1776, at Baltimore; March 4, 1777, at Philadelphia; Sept. 27, 1777, at Lancaster, Pa.; Sept. 30, 1777, at York, Pa.; July 2, 1778, at Philadelphia; June 30, 1783, at Princeton, N.J.; Nov. 26, 1783, at Annapolis, Md.; Nov. 1, 1784, at Trenton, N.J.; and Jan. 11, 1785, at New York. The latter continued to be the meeting place

until the adoption of the U.S. constitution. From 1781 to 1788, congress met annually on the first Monday in November as provided in the articles of confederation.

**CONTINENTAL DIVIDE:** *see DRAINAGE BASIN.*

**CONTINENTAL SHELF**, the submerged margin of a continental platform (*see CONTINENT*). The surface of the earth lies at two general levels: a lower, which is the floor of the ocean basins, and an upper, the parts of which are the continents. Between these two levels is a comparatively narrow slope. The volume of ocean water is, however, a little too great to be entirely contained in the ocean basins, and so it must lap over somewhat on the lower, outer edges of the continental platforms. Such a submerged outer edge is called the continental shelf.

The shelf varies greatly in width. Almost everywhere it represents simply a continuation of the land surface beneath the ocean margins; hence, it is broad and relatively level offshore from plains, and narrow, rough and steep off mountainous coasts. The shelf thus is narrow off the mountainous western coast of the United States, and wide off the east coast of the United States and off the northwest coast of Europe surrounding the British Isles. Hudson bay is simply a part of the continental shelf.

Some parts of the world's continental shelves are extremely level—for example, that part off the arctic coast of Siberia—but more commonly they exhibit some relief. Close to the coast of New England are submerged glacial deposits. In places ridges or cliffs can be traced from the land onto the continental shelf.

River valleys that have been formed on land and then inundated can be mapped by soundings of the ocean floor on the submerged continental shelf. Where the sea has risen considerably relative to the land, cliffs formed by wave erosion when the ocean stood at a lower level may be submerged 200 ft. or more.

On most of the continental shelves of the world are developed extraordinarily deep canyons, the largest as much as 2,000 or 3,000 ft. deep. The sides of some of these are great vertical cliffs, but others are V-shaped like many youthful land valleys, though in general they are straighter than land valleys. Some of them connect with a system of land valleys, but their origin is one of the great scientific puzzles. (W. C. C.)

**CONTINENTAL SYSTEM**, the name given to Napoleon's design for paralyzing Great Britain through the destruction of British commerce. The decrees of Berlin (Nov. 21, 1806) and Milan (Dec. 17, 1807) proclaimed a blockade: neutrals and French allies were not to trade with the British.

To this "continental system" England responded by orders in council which subjected France and all countries in alliance with Napoleon to a counterblockade.

The campaign of starvation brought great suffering to the belligerents and vast annoyance to neutrals. It was one of the main causes of the Anglo-American War of 1812. But since the British had an overwhelming superiority at sea, the contest proved disastrous to Napoleon—not only because of the resulting privations, but also because to maintain his system he had to take on responsibilities too great for him. *See NAPOLEONIC WARS; WAR OF 1812.*

**CONTINUED FRACTIONS.** A continued fraction is obtained from a sequence of ordinary fractions  $a_1/b_1, a_2/b_2, a_3/b_3, \dots$ , called partial quotients, by adding each fraction to the denominator of the preceding fraction of the sequence, thus:

$$\begin{array}{r} a_1 \\ \hline b_1 + \frac{\quad}{\quad} \\ \hline a_2 \\ \hline b_2 + \frac{\quad}{\quad} \\ \hline a_3 \\ \hline b_3 + \frac{\quad}{\quad} \\ \hline \end{array}$$

(see FRACTION). To this may be added a number  $b_0$ . Each partial numerator  $a_p$  and partial denominator  $b_p$  may be any real or complex number. The continued fraction may terminate, or there may be infinitely many partial quotients. The ordinary fractions

$$\frac{A_0}{B_0} = \frac{b_0}{1}, \frac{A_1}{B_1} = \frac{b_0 b_1 + a_1}{b_1}, \frac{A_2}{B_2} = \frac{b_0 b_1 b_2 + a_1 b_2 + a_2 b_0}{b_1 b_2 + a_2}, \dots$$

obtained by cutting off the continued fraction with the successive partial quotients are called the approximants. These may be computed by means of the fundamental recurrence formulas

$$\begin{aligned} A_p &= b_p A_{p-1} + a_p A_{p-2}, \\ B_p &= b_p B_{p-1} + a_p B_{p-2}, \end{aligned} \quad p = 2, 3, 4, \dots$$

starting with the initial values  $A_0 = b_0$ ,  $A_1 = b_0 b_1 + a_1$ ,  $B_0 = 1$ ,  $B_1 = b_1$ . If the denominators  $B_p$  are different from zero from and after some value of  $p$ , and the sequence of approximants converges to a finite limit  $V$ , then the continued fraction is said to converge, and  $V$  is called its value. Otherwise the continued fraction is said to be divergent, and is assigned no value.

Continued fractions occupy an important place in mathematics because of their interesting properties and their connections with many different branches of science: number theory, theory of equations, probability, summability, theory of integration, infinite matrices and the theory of functions. They find applications in the physical sciences; for instance, in the theory of electrical networks and in certain problems in dynamics.

**Convergence and Divergence.**—It is easily seen that the values of the approximants of the continued fraction are unchanged if  $a_p$  and  $b_p$  are replaced by  $c_{p-1}c_p a_p$  and  $c_p b_p$ , respectively ( $p = 1, 2, 3, \dots$ ), where  $c_0 = 1$ , and  $c_1, c_2, c_3, \dots$  is any number sequence with none of its terms zero. This is called an equivalence transformation. If the  $a_p$  are different from zero, the  $c_p$  can be chosen so that the transformed continued fraction has all its partial numerators equal to unity.

Similarly, if the  $b_p$  are different from zero, the continued fraction is equivalent to another whose partial denominators are equal to unity. Thus, most continued fractions can be written in the forms

$$(A) \quad b_0 + \frac{1}{b_1 + \frac{1}{b_2 + \frac{1}{b_3 + \dots}}} \quad \text{and} \quad (B) \quad b_0 + \frac{a_1}{1 + \frac{a_2}{1 + \frac{a_3}{1 + \dots}}}$$

If the denominators  $B_p$  of the continued fraction are different from zero, then the continued fraction is equivalent, in a certain sense, to the infinite series

$$\frac{A_0}{B_0} + \sum_{p=1}^{\infty} \left( \frac{A_p}{B_p} - \frac{A_{p-1}}{B_{p-1}} \right)$$

In fact, the sum of the first  $n$  terms of this series is precisely the  $n$ th approximant of the continued fraction (see SERIES). If the series converges, its sum is the value of the continued fraction, and if the series diverges, the continued fraction diverges. The general term of the series is  $(-1)^{p-1} a_1 a_2 \dots a_p / B_p B_{p-1}$ . This is an immediate consequence of the determinant formula

$$A_p B_{p-1} - A_{p-1} B_p = (-1)^{p-1} a_1 a_2 \dots a_p$$

which is readily obtainable from the fundamental recurrence formulas.

By way of illustration, consider the so-called simple continued fraction, which is of the form (A) where  $b_0$  is an integer, and each of  $b_1, b_2, b_3, \dots$  a positive integer. Then, each  $B_p$  is a positive integer, and  $B_0 \leq B_1 < B_2 < B_3 < \dots$ . The above series is now

$b_0 + \sum_{p=1}^{\infty} (-1)^{p-1} / B_p B_{p-1}$ . This is an alternating series in which the terms decrease numerically to the limit zero, and is therefore convergent. Hence the simple continued fraction is convergent. If  $V$  is its value, then the alternating character of the series shows that the even approximants increase to the limit  $V$ , the odd approximants decrease to the limit  $V$ , and

$$\left| V - \frac{A_n}{B_n} \right| \leq \frac{1}{B_n B_{n+1}} < \frac{1}{B_n^2}$$

If the series  $\sum |b_p|$  converges, then (A) is divergent. Thus, a necessary condition for (A) to converge is that the series  $\sum |b_p|$  diverge. This condition is sufficient only when the  $b_p$  are subject to certain restrictions; e.g., if the  $b_p$  are real and positive, or if  $b_1 \neq 0$  and  $0 < c \leq \arg b_p \leq \pi - c$ ,  $p = 1, 2, 3, \dots$ , where  $c$  is a positive number. It may easily be verified that if  $b_p = (-1)^{p+1}$ , then (A) is divergent although the series  $\sum |b_p|$  diverges.

The continued fraction (B) converges if  $|a_p| \leq 1/4$ ,  $p = 2, 3, 4, \dots$ . On the other hand, it diverges if  $a_p = -1/4 - c$ ,  $p = 1, 2, 3, \dots$ , where  $c$  is a positive number. For convenience, let  $b_0 = 0$  and  $a_1 = 1$  in (B). In the plane of the complex variable  $z = x + iy$ , let  $W$  denote any bounded subset of the parabolic disk defined by  $y^2 \leq x + 1/4$  (see SET THEORY [THEORY OF AGGREGATES]). If each of the partial numerators  $a_2, a_3, a_4, \dots$  of (B) is in  $W$ , then (B) converges and its value is in the circular disk defined by  $x^2 - 2x + y^2 \leq 0$ . The statement concerning convergence of (B) is no longer true if the parabolic disk is replaced by a region having the parabolic disk as a proper subset.

These statements may perhaps serve to indicate some of the remarkable convergence properties of continued fractions.

**Arithmetic Theory.**—It has been shown that the simple continued fraction is convergent. Every real number has a simple continued-fraction expansion, which terminates if and only if the number is rational. To obtain the expansion of a rational fraction, the familiar Euclidean algorithm for the greatest common divisor is used. For example,  $31/17 = 1 + 14/17$ ,  $17/14 = 1 + 3/14$ ,  $14/3 = 4 + 2/3$ ,  $3/2 = 1 + 1/2$ , so that

$$\begin{aligned} \frac{31}{17} &= 1 + \frac{1}{17} \\ &= 1 + \frac{1}{4 + \frac{1}{1 + \frac{1}{2}}} \end{aligned}$$

To expand an irrational number  $w$ , put  $w = b_0 + w_1$ , where  $b_0$  is the largest integer less than  $w$ , so that  $0 < w_1 < 1$ . Then put  $1/w_1 = b_1 + w_2$ , where  $b_1$  is the largest integer less than  $1/w_1$ , so that  $0 < w_2 < 1$ . Continuation of this process gives step by step the simple continued-fraction expansion (A) for the number  $w$ . For example, if  $w = \sqrt{7}$ , then  $w_1 = \sqrt{7} - 2$ ,  $w_2 = (\sqrt{7} - 1)/3$ ,  $w_3 = (\sqrt{7} - 1)/2$ ,  $w_4 = (\sqrt{7} - 2)/3$ ,  $w_5 = \sqrt{7} - 2 = w_1$ . Therefore,  $b_0 = 2$ ,  $b_1 = 1$ ,  $b_2 = 1$ ,  $b_3 = 1$ ,  $b_4 = 4$ ,  $b_5 = 1$ ,  $\dots$ . The partial denominators run 1, 1, 1, 4, 1, 1, 1, 4, 1, 1, 4,  $\dots$ , repeating in blocks of four. Thus, the continued fraction is periodic. It can be shown that every quadratic surd has a periodic expansion, and that every periodic simple continued fraction is equal to a quadratic surd. From the above example the following approximations to  $\sqrt{7}$  are found  $2/1$ ,  $3/1$ ,  $5/2$ ,  $8/3$ ,  $37/14$ ,  $45/17$ ,  $\dots$ . These fractions are alternately less than and greater than  $\sqrt{7}$ .

It is easy to obtain the value of a periodic continued fraction. For example, let  $b_0 = 1$ ,  $b_p = 2$ ,  $p = 1, 2, 3, \dots$ . Then if  $v$  is the value,  $(v + 1) = 2 + 1/(v + 1)$ ,  $(v + 1)^2 - 2(v + 1) - 1 = 0$ ,  $v = \pm \sqrt{2}$ . And since  $v$  is not negative, then  $v = \sqrt{2}$ .

The rational approximants for  $\sqrt{N}$  obtained from the simple continued fraction have interesting geometrical properties. Consider the equation  $x^2 - Ny^2 = h$ , where  $h$  is an integer. This may be written in the form  $(x/y) - \sqrt{N} = h/[(x/y) + \sqrt{N}]y^2$ . If  $x = A_n$  and  $y = B_n$  the left-hand member of this equality is less in absolute value than  $1/y^2$ , and therefore  $|h| < (A_n/B_n) + \sqrt{N}$ , so that  $|h| \leq 2\sqrt{N}$ . This shows that the set  $A_n^2 - NB_n^2$ ,  $n = 0, 1, 2, \dots$ , is finite. Geometrically, this means that there is a finite set of hyperbolas each having the line  $x - \sqrt{N}y = 0$  as asymptote, such that for every  $n$  the point with co-ordinates  $(A_n, B_n)$  lies on one of them. If  $N = 7$ , the first six of these points are (as indicated above)  $(2, 1)$ ,  $(3, 1)$ ,  $(5, 2)$ ,  $(8, 3)$ ,  $(37, 14)$ ,  $(45, 17)$ . There are in this case three hyperbolas, namely  $x^2 - 7y^2 = 1$ ,  $x^2 - 7y^2 =$

2,  $x^2 - 7y^2 = -3$ . The equation  $x^2 - Ny^2 = 1$  is called Pell's equation. It can be shown that every solution in positive integers of Pell's equation is of the form  $x = A_n$ ,  $y = B_n$ , where  $A_n/B_n$  is the  $n$ th approximant of the simple continued fraction for  $\sqrt{N}$ .

Irrational numbers which are not quadratic surds have infinite, nonperiodic, simple continued fractions. For example, in the simple continued fraction for  $e = 2.71828 \dots$ ,  $b_0 = 2$ , and  $b_1, b_2, b_3, \dots$  are 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8,  $\dots$ . In the case of  $\pi = 3.14159 \dots$ ,  $b_0 = 3$ , and  $b_1, b_2, b_3, \dots$  are 7, 15, 1, 292, 1, 1, 1, 2,  $\dots$ , where the law of formation is not known. The numbers  $e$  and  $\pi$  have been proved to be transcendental; i.e., they are not roots of algebraic equations with integral coefficients. Historically, the first proof of the existence of transcendental numbers was given by Joseph Liouville by means of continued fractions. He showed that if, for each positive integer  $n$ , there exists an index  $k$  such that  $b_{k+1} > B_n^k$ , then the value of the simple continued fraction is a transcendental number. For example,  $b_{k+1} = 1 + B_k^k$ ,  $k = 0, 1, 2, \dots$ ; i.e.,  $b_1 = 2$ ,  $b_2 = 3$ ,  $b_3 = 50, \dots$ .

**Analytic Theory, Applications.**—The most important continued fractions in the analytic theory are

$$(C) \frac{1}{b_1 + z - \frac{1}{a_1^2 + \frac{1}{b_2 + z - \frac{1}{a_2^2 + \frac{1}{b_3 + z - \dots}}}}} \quad \text{and} \quad (D) \frac{1}{k_1 z + \frac{1}{k_2 z + \frac{1}{k_3 z + \frac{1}{k_4 z + \dots}}}}$$

Here each  $a_p$  and  $k_p$  is a number not zero, each  $b_p$  a number and  $z$  is a complex variable; (C) is called a Jacobi-fraction or J-fraction, and (D) is called a Stieltjes-fraction or S-fraction. The J-fraction is closely related to the Jacobi-matrix or J-matrix, which is the infinite matrix of coefficients of the system of equations

$$-a_p x_p + (b_p + z)x_{p+1} - a_{p+1}x_{p+2} = 0, \quad p = 0, 1, 2, \dots, (a_0 = 0)$$

The notation is chosen in (C) so as to avoid square roots in the coefficients in this matrix. The theory of the J-fraction may be regarded as a part of D. Hilbert's theory of infinite matrices and quadratic forms in infinitely many variables (see MATRIX).

T. J. Stieltjes used the continued fraction (D), with the  $k_p$  real and positive, to solve his celebrated moment problem. Let  $x_1, x_2, x_3, \dots$  be an increasing sequence of points along the positive half of the  $x$ -axis, and let  $m_p$  be a positive mass concentrated at  $x_p$ . If the sums  $c_p = \sum_{k=1}^{\infty} x_k^p m_k$ ,  $p = 0, 1, 2, \dots$ , exist

they are called the moments of the distribution of mass. The Stieltjes moment problem is the problem of determining a distribution of mass which will have preassigned moments  $c_0, c_1, c_2, \dots$ . Stieltjes found that the problem has a solution if and only if the formal power series  $\sum_{p=0}^{\infty} (-1)^p c_p / z^{p+1}$  has an S-fraction

expansion (D) in which the  $k_p$  are positive. He then constructed from the S-fraction by successive approximation a system of masses having the given moments. He had to permit continuous as well as discontinuous distributions of mass. Moreover, there is just one solution of the moment problem if the series  $\sum k_p$  diverges. In this case, the S-fraction converges to a function of the form  $\int_0^{\infty} dm(u)/(z+u)$ . The function  $m(u)$  then gives the distribution of mass, and  $c_p = \int_0^{\infty} u^p dm(u)$ ,  $p = 0, 1, 2, \dots$ . If the series  $\sum k_p$  converges, then the problem has infinitely many different solutions.

This moment problem has been extended and applied in various directions. For instance, the ideas of Stieltjes formed much of the background for Hilbert's famous theory of quadratic forms in infinitely many variables; they were used by Felix Hausdorff in his method of summing divergent series; and T. Carleman applied the theory to prove fundamental theorems on quasi-analytic functions. The more general problem in which a distribution of mass is allowed along the entire real axis has been solved by means of J-fractions.

An important role of the continued fraction is to serve as an

intermediary between a divergent power series and a definite integral. If the power series has a J-fraction or S-fraction expansion of suitable type, then it is asymptotically equal to one or more definite integrals of the form  $\int_{-\infty}^{\infty} dm(u)/(z+u)$ . Con-

sider, for example, the totally divergent series  $\sum_{p=0}^{\infty} (-1)^p p! / z^{p+1}$ .

This has the S-fraction expansion (D) in which  $k_1 = 1$ ,  $k_2 = 1$ ,  $k_3 = 1$ ,  $k_4 = 1/2$ ,  $k_5 = 1/3$ ,  $k_6 = 1/4, \dots$ . This S-fraction converges, and its value is  $\int_0^{\infty} e^{-u} du/(z+u)$ , a function which may be regarded as the "sum" of the divergent series. The continued fraction can be used in this way to connect divergent series with definite integrals in a wide variety of problems. Continued fractions are used to construct electrical networks having preassigned properties embodied in a given function. If this function is expanded into a continued fraction the characteristics of the required network can be read off immediately.

In certain problems of stability of dynamical systems it is important to have a simple algorithm for deciding whether or not all the zeros of a polynomial  $P(z) = z^n + a_1 z^{n-1} + a_2 z^{n-2} + \dots$  have negative real parts. In case the coefficients  $a_p$  are real, it is only necessary to expand  $Q(z)/P(z)$ , where  $Q(z) = a_1 z^{n-1} + a_2 z^{n-2} + \dots$ , into a continued fraction of the form

$$\frac{1}{c_1 z + \frac{1}{c_2 z + \frac{1}{c_3 z + \frac{1}{c_4 z + \dots}}}}$$

The required criterion is that the  $c_p$  be positive. This expansion can be obtained by ordinary long division. If  $k$  of the  $c_p$  are positive and  $n-k$  are negative, then  $k$  of the zeros of the polynomial have negative real parts and  $n-k$  have positive real parts. This algorithm may be modified to cover polynomials with arbitrary complex coefficients.

Continued fractions are often useful in computing values of functions. For example, perhaps the best way to compute values of the integral  $\int_0^{\infty} e^{-x^2} dx$  is to use the expansion  $\sqrt{\pi}/2 - e^{-K^2}$ , where  $K$  is the continued fraction in which  $b_0 = 0$ , the sequence of partial numerators is 1, 1, 2, 3, 4, 5,  $\dots$ , and the sequence of partial denominators is  $2a, a, 2a, a, 2a, a, \dots$ . Carl F. Gauss obtained a continued-fraction expansion for the quotient  $F(a, b+1, c+1; z)/F(a, b, c; z)$  of contiguous hypergeometric functions. By specializing the parameters  $a, b, c$ , one may obtain expansions for many particular functions.

It is natural to ask whether or not it is possible to express, in a simple way, the sum, difference, product or quotient of two continued fractions as a continued fraction. The answer is in the negative. The operations of differentiation and integration are not suited to continued fractions. The operations which can be performed stem from the fact that a continued fraction is essentially the symbolic product of infinitely many linear fractional transformations in the complex plane. It may also be regarded as arising from a single linear transformation in the space of infinitely many variables. From the first point of view, the continued-fraction theory becomes a part of the theory of Möbius transformations; while from the second point of view, it becomes a part of the theory of infinite matrices and of quadratic forms in infinitely many variables. See also NUMBERS, THEORY OF; TRANSCENDENTAL NUMBERS.

**BIBLIOGRAPHY.**—Several treatises on algebra have chapters on the arithmetic theory of continued fractions. The book of H. S. Wall, *Analytic Theory of Continued Fractions* (1948), deals with questions of convergence and the function-theoretic aspects of continued fractions. The paper of J. S. MacNerney, "Investigation Concerning Positive Definite Continued Fractions," *Duke Math. J.*, vol. 26 (1959), deals with continued fractions whose partial numerators and denominators are matrices. (H. S. Wall.)

**CONTINUITY.** The mathematical concept of continuity occurs in geometry and in the theory of functions, and so enters

into their applications to the physical world. Intuitively, an entity is regarded as continuous if it is unbroken; that is, has no gaps. Physical space and time are commonly considered as continuous. On the other hand matter is discrete; that is, it is made up of particles which are separated in space. However, for convenience, matter is frequently treated as if it were continuous, whenever such treatment gives a sufficiently close approximation to the observed facts.

An "equation of continuity" occurs in many branches of physics; for example, see MECHANICS, FLUID.

More precise definitions follow. In geometry, a straight line is said to be continuous if the following conditions hold true: (1) between every two points on the line there is a third point on the line; and (2) whenever the line is separated into two pieces there is always an extreme point on one of the pieces which may be taken to define the separation. This property of the straight line is an assumption or postulate, and geometric systems have been studied in which it is absent (see LINE). The continuity property of the real number system consists of two corresponding parts: (1) between every two real numbers there is a third real number; and (2) if the real numbers are separated into two subclasses A and B such that every number in A is less than every number in B, then either A contains a greatest number, or else B contains a least number. For the real numbers this property may be proved (see NUMBER). Thus the possibility of setting up a correspondence between the real numbers and the points on a line, such as lies at the basis of analytic geometry, depends on the continuity postulate in geometry. The rational numbers do not form a continuous system according to the definition above, since, for example, if A consists of all negative rational numbers and all positive rational numbers whose squares are less than two, and if B consists of the remaining rational numbers, then A contains no greatest number, and B contains no least.

A function  $f(x)$  is said to be continuous at a point  $c$  if it has a value at  $c$  and if  $f(x)$  approaches  $f(c)$  when  $x$  approaches  $c$  (see FUNCTION). A function is continuous in a domain if it is continuous at every point of the domain. A continuous curve in a plane in which an  $xy$ -co-ordinate system has been set up consists of the points given by two continuous functions  $x = f(t)$ ,  $y = g(t)$  of a real variable  $t$  on an interval  $a \leq t \leq b$ . In topology the notion of continuous curve is used in a somewhat different but equivalent sense (see TOPOLOGY, GENERAL).

**CONTINUO (BASSO CONTINUO):** see THOROUGH BASS.

**CONTINUOUS VOYAGE**, the doctrine in international law that a voyage by way of an intermediate port is in fact continuous. During the Napoleonic Wars, U.S. merchants attempted to evade British blockade restrictions by carrying goods from the French West Indies to France via U.S. ports. British courts ruled that such voyages were in fact continuous and were not entitled to be considered neutral commerce. The U.S. federal government upheld the doctrine in the American Civil War in cases involving British transshipment of goods to the Confederate states. See CONTRABAND; NEUTRALITY.

**CONTOUR FARMING** is the practice of following the contour of the land in cultivation to reduce soil losses from surface erosion and to conserve water in the small furrows. In contour farming the plowman keeps to a level line at right angles to the direction of the slope, the usual result being furrows that curve around the slope and are level.

The early Phoenicians practised terracing and contour cultivation and through their colonizing spread the practice the length of the Mediterranean. In Rome, however, and later in Britain, Europe and the United States, the standard became cultivation in straight furrows rather than with regard to slope.

In the 20th century, agricultural research showed that contour farming reduced soil and water losses, the soil loss on 2% to 8%

contoured slopes not more than 300 ft. long being about half that with straight-row cultivation. Dust storms in the U.S. Great Plains area in the 1930s focused new attention on soil erosion, conservation problems and practices including contouring. Demonstrations showed that contouring could, under ideal conditions, increase yields of row crops as much as 50%; increases of 5% to 10% were common. The practice also was extended to contour strip cropping (with strips of close-sown crops alternating with strips of other crops to slow down the run-off) and to contour furrowing of range land.

See SOIL: Soil Erosion and Conservation.

**CONTOUR LINE**, a line on a map, representing an imaginary line on the land surface all points of which are at the same elevation above a datum plane, usually mean sea level. Imagine a land surface inundated by the sea to a depth of 100 ft.; that is, the intersection of a horizontal plain with the uneven surface of the land. If then a line representing the edge of the sea is drawn on a map of the area, the result would be a contour line, and it would be called the 100-ft. contour. Similar contours could be drawn at successive 100-ft. intervals or at any desired interval. See also MAP.

(W. C. C.)

**CONTRABAND**. The restrictions upon the mutual conduct of belligerents and neutrals that were being formulated from the later middle ages on involved the classification of certain supplies as contraband. Belligerents claimed the continuing liberty to appropriate these if they captured them on the way to an enemy. About weapons there could be little controversy; but in regard to things of less immediate military use wide diversity marked both theory and practice.

In his *De jure belli ac pacis*, first published in 1625, Hugo Grotius took note of an already old controversy as to what kind of things might properly be treated in the same way as weapons. He suggested a threefold division which might well have served as a rational solution. Things designed for use in war would always be subject to seizure on their way to enemy territory; things of no military value would always be exempt; and things necessary both in peace and in war would be seizable only if victory depended upon preventing their supply to the enemy. From time to time thereafter classifications on similar lines were advocated by writers or governments, with no visible effect upon practice. Governments issued proclamations at the beginning or in the course of hostilities listing the things they would seize, and these differed from country to country and from one set of wartime circumstances to another. The numerous treaties by which governments sought to limit such restrictions upon the trade of their nationals when neutral, while preserving as much liberty as possible when belligerent, varied too greatly to set anything resembling a fixed pattern. Naval stores and horses were included or excluded as the changing interests of the parties dictated; food and forage appeared in some contraband lists though they were excluded from most; and even saltpetre, an essential component of gunpowder, was sometimes left on the free list.

It was not the neutral state but the owners, and in some circumstances the carriers, that suffered the penalties for shipping contraband. Belligerents asserted the right to visit and search neutral ships, to confiscate contraband found aboard, and, if this exceeded a certain proportion of the cargo, was concealed by false papers or belonged to the shipowner, to take the ship itself as prize.

As for any responsibility attaching to the neutral state as such for supplies from its nationals to belligerents, this began to be acknowledged only after 1873, when the United States and Great Britain submitted to arbitration the depredations of the "Alabama" and other vessels fitted out in British territory for Confederate service in the American Civil War. (See "ALABAMA" ARBITRATION.) Even then, the arbitration covered only the building or fitting out of ships of war. The principle, adopted for the purposes of that arbitration, that neutral governments must use "due diligence" to prevent the construction or equipment of warships for belligerent service was recorded in Hague convention XIII of 1907 though the term "means at its disposal" was substituted for "due diligence." The principle was extended to military aircraft in the unratified air rules, drawn up at The Hague in 1923, which

attempted to adapt the surviving principles of maritime contraband to war in the air.

The stronger naval powers tended to expand the lists of contraband, for, having the means of protecting their own supply, they could weaken an enemy by cutting off his trade in essential commodities. The rudiments of economic warfare were understood long before the term came into use. Thus England, in opposition to the continental powers, and for some time to the United States as well, asserted the liberty to take provisions on their way to enemy forces or ports of naval supply. It was the gradual extension of this practice in the 19th century to a variety of goods necessary in war as in peace, with the U.S. contributing after 1812, that led to the general recognition of conditional contraband.

In 1908-1909 ten naval powers met in London to draw up an agreed code regarding belligerent restrictions on neutral trade for the guidance of the International Prize court that had been proposed at the Hague Peace conference of 1907. The resulting declaration of London classified goods as (1) absolute contraband; (2) conditional contraband; and (3) free. The first class was open to seizure on its way to any destination in enemy territory. In addition to arms, munitions and military equipment, it included horses. The second consisted of things such as food, clothing, money, rolling-stock, together with flying machines, which were to be treated as contraband only if in transit to the government or armed forces of an enemy. The third class listed goods not subject to capture.

Though never ratified, the declaration of London was near enough to a general consensus to be provisionally adopted on both sides when war broke out in 1914. But the demands of total war soon demonstrated the futility of such advance distinctions in supplies. Flying machines had become an essential weapon; articles such as rubber, cotton and even soap were moved from the free list to that of absolute contraband; and the taking over of import trade by the belligerent governments eliminated the difference of destination that had separated absolute from conditional contraband. The declaration was explicitly discarded in 1916.

Traditionally, destination was of the essence of contraband. Goods shipped by one neutral to another were in principle innocent. But British and American practice in the 19th century extended the liberty of seizure to goods which, though on their way to an immediate neutral destination, were to be forwarded to an enemy. In such cases the whole transportation, though broken by transshipment, was deemed one continuous voyage and, if goods satisfied the other conditions, those captured in the first part of the voyage were treated as contraband. This extension was recognized in the declaration of London, but, save where the receiving belligerent had no seaport, only in reference to absolute contraband. This exception in favour of conditional contraband was ignored in World War I. Insofar as destination still determined the guilt or innocence of a shipment, it was now uniformly ultimate destination.

Clearly the trend was toward full liberty to deprive an enemy of all benefit of neutral trade. This was emphasized between 1914 and 1918 by the Allied imposition of quotas upon European neutrals to prevent them from supplying the enemy with goods from their own stocks which they would then replace from foreign sources. The quotas were fixed by reference to the average peacetime requirements of the neutral country, and any excess was subject to appropriation by a belligerent. Even ultimate neutral destination of a particular shipment thus ceased to ensure exemption. The centuries-old effort to maintain, by distinctions in the nature of goods and their immediate destination, a measure of commercial liberty for nations remaining at peace, was approaching final defeat.

The swiftness of this development in its later stages was due to changes in the nature and scope of war. From a contest of armed forces, war had become a struggle engaging the entire corporate energies of nations. Anything sustaining those energies was legitimate prey to a belligerent. All commercial interchange, even between neutrals, was subject to interruption. As more and more nations were drawn into the fray, the neutral strength which had been a major factor in restraining belligerent action faded away.

Economic strangulation, little hampered by the rules regarding contraband and blockade that 19th-century doctrine and treaties had sought to build into an effective code, became a principal weapon for nations equipped to use it. Where legal justification was thought useful, it was found in the notion of retaliation for violation of law by the enemy. In fact law, hobbled by the demands of modern war, could here keep no pace with power.

When in 1939 proclamations issued by the Allied powers and by Germany again differentiated between absolute and conditional contraband, listing food, forage and clothing under the latter head, this listing did not substantially enlarge the commercial liberties of neutrals. The only secure maritime trade left to them was that covered by the naval certificates ("navicerts") issued by belligerents to approved shippers and cargoes. This practice, already resorted to in World War I, was greatly extended in World War II. Its widespread adoption amounted to official assertion and acknowledgment that in time of war trade by sea was by belligerent licence. See also ECONOMIC WARFARE; NEUTRALITY.

**CONTRACEPTION:** see BIRTH CONTROL.

**CONTRACT.** The simplest definition of a contract is that it is a promise enforceable by law. If the promise is broken, the remedy sometimes is specific or actual performance of what was promised, but generally is compensatory damages. A usual requisite of a contractual promise is that it must be the product of a bargain; i.e., the person to whom the promise is made (the promisee) must give to the person making the promise (the promisor) something in exchange for the promise. The thing given in exchange (called consideration) may be an act, like the payment of money, performance of service, the transfer of real or personal property, a forbearance to act or the making of a return promise of any of these things. Hence a contract may involve a promise on one side only, in which case it is unilateral, or it may consist of promises on both sides, in which case it is bilateral.

Since a contract is usually a type of bargain, the making of a contract requires the mutual assent of two or more persons. This means that ordinarily there must be an offer by one person (the offeror) and an acceptance by another (the offeree). An offer is a manifestation of an intention to contract on the basis of stated terms, and an acceptance is an appropriate manifestation of assent to those terms. It is usually the reasonable impression created and not the subjective intent of the parties that is significant.

An offer must be accepted within the time specified by it or, if no time is specified, a reasonable time. An offeror also may prescribe the mode of acceptance, but in the absence of such a prescription the offeree may use any reasonable or customary mode.

If the parties deal with each other face to face or by telephone, it is usually assumed that, since instantaneous communication is possible, the acceptance must be communicated (i.e., heard) before it is effective. However, if they are at a distance from each other and if an acceptance by mail, telegram or radiogram is authorized by the offer, the question of when the contract is closed is a debatable one. In the interest of the expeditious closing of commercial transactions, English and nearly all U.S. authorities support the view that the contract is made when the offeree sends the communication of acceptance.

Unless an offeror receives consideration for holding an offer open, he may revoke it with impunity at any time before it is accepted, and a revocation is accomplished by any notice thereof that reaches the offeree.

An adequate description of a contract must include the legal consequences as well as the facts necessary to its creation. The traditional term used to describe these consequences is obligation.

Obligation here means legal duty. One who makes a contractual promise to do an act comes under a legal duty to do the act. Correlatively, the promisee acquires against the promisor a legal right (or claim) that the act shall be done. This means that if the act is not done (there being no legal excuse), the promisee may pursue his judicial remedy against the promisor.

(G. W. Go.)

## HISTORY

Enforcement of good faith in matters of bargain and promise is among the most important functions of legal justice. It might not be too much to say that, next after keeping the peace and securing property against violence and fraud so that business may be possible, it is the most important. Yet we shall find that the importance of contract is developed comparatively late in the history of law. The commonwealth needs elaborate rules about contracts only when it is advanced enough in civilization and trade to have an elaborate system of credit. The Roman law of the empire dealt with contract, indeed, in a fairly adequate manner, though it never had a complete or uniform theory; and the Roman law, as settled by Justinian, appears to have satisfied the eastern empire long after the western nations had begun to recast their institutions and the traders of the Mediterranean had struck out a cosmopolitan body of rules and custom known as the law merchant, which claimed acceptance in the name neither of Justinian nor of the church but of universal reason. It was amply proved afterward that the foundations of the Roman system were strong enough to carry the fabric of modern legislation. But the collapse of the Roman power in western Christendom threw society back into chaos.

In this condition of legal ideas, which it would be absurd to call jurisprudence, the general duty of keeping faith is not recognized except as a matter of religious or social observance. Those who desire to be assured of anything that lies in promise must exact an oath, or a pledge, or personal sureties; and even then the court of their people—in England the hundred court in the first instance—will do nothing for them in the first case, and not much in the two latter. Probably the settlement of a blood feud, with provisions for the payment of the fine by installments, was the nearest approach to a continuing contract, as we now understand the term, which the experience of Germanic antiquity could furnish. It is also probable that the performance of such undertakings, as it concerned the general peace, was at an early time regarded as material to the commonweal; and that these covenants of peace, rather than the rudimentary selling and bartering of their day, first caused our Germanic ancestors to realize the importance of putting some promises at any rate under public sanction. The history of the law, and even the form of much law still common to almost all the English-speaking world, can be understood only when we bear in mind that our forefathers did not start from any general conception of the state's duty to enforce private agreements, but, on the contrary, the state's powers and functions in this regard were extended gradually, unsystematically and by shifts and devices of ingenious suitors and counsel, aided by judges, rather than by any direct provisions of princes and rulers. Money debts, it is true, were recoverable from an early time. But this was not because the debtor had promised to repay the loan; it was because the money was deemed still to belong to the creditor, as if the identical coins were merely in the debtor's custody. The creditor sued to recover money, for centuries after the Norman Conquest, in exactly the same form which he would have used to demand possession of land; the action of debt closely resembled the "real actions," and, like them, might be finally determined by a judicial combat; and down to Sir William Blackstone's time the creditor was said to have a property in the debt—property which the debtor had "granted" him. Giving credit, in this way of thinking, is not reliance on the right to call hereafter for an act, the payment of so much current money or its equivalent, to be performed by the debtor, but merely suspension of the immediate right to possess one's own particular money, as the owner of a house let for a term suspends his right to occupy it. This was no road to the

modern doctrine of contract, and the passage had to be made another way.

In fact the old action of debt covered part of the ground of contract only by accident. It was really an action to recover any property that was not land; for the remedy of a dispossessed owner of chattels, afterward known as *detinue*, was only a slightly varying form of it. If the property claimed was a certain sum of money, it might be due because the defendant had received money on loan or because he had received goods of which the agreed price remained unpaid; or, in later times at any rate, because he had become liable in some way by judgment, statute or other authority of law to pay a fine or fixed penalty to the plaintiff. Here the person recovering might be as considerable as the lord of a manor or as mean as a "common informer"; the principle was the same. In every case outside this last class—that is to say, whenever there was a debt in the popular sense of the word—it had to be shown that the defendant had actually received the money or goods; this value received came to be called *quid pro quo*—a term unknown, to all appearance, out of England. Nevertheless, the foundation of the plaintiff's right was not bargain or promise but the unjust detention by the defendant of the plaintiff's money or goods.

**Modes of Proof.**—We are not concerned here to trace the change from the ancient method of proof—oath backed by "good suit," *i.e.*, the oaths of an adequate number of friends and neighbours—through the earlier form of jury trial, in which the jury were supposed to know the truth of their own knowledge, to the modern establishment of facts by testimony brought before a jury who are bound to give their verdict according to the evidence. But there was one mode of proof which, after the Norman Conquest, made a material addition to the substantive law. This was the proof by writing, which means writing authenticated by seal. Proof by writing was admitted under Roman influence, but, once admitted, it acquired the character of being conclusive which belonged to all proof in early Germanic procedure. Oath, ordeal and battle were all final in their results. When the process was started there was no room for discussion, though any formal irregularity was fatal. So the sealed writing was final too, and a man could not deny his own deed. We still say that he cannot, but with modern refinements. Thus the deed, being allowed as a solemn and probative document, furnished a means by which a man could bind himself, or rather effectually declare himself bound, to anything not positively forbidden by law. Whoever could afford parchment and the services of a clerk might have the benefit of a "formal contract" in the Roman sense of the term. In modern times the form of deed called a bond or "obligation" is, as it stands settled after various experiments, extremely artificial; but it is essentially a solemn admission of liability, though its conclusive stringency has been relaxed by modern legislation and practice in the interest of substantial justice. By this means the performance of all sorts of undertakings, pecuniary and otherwise, could be and was legally secured. Bonds were well known in the 13th century, and from the 14th century onward were freely used for commercial and other purposes; as for certain limited purposes they still are. The "covenant" of modern draftsmen is a direct promise made by deed; it occurs mainly as incident to conveyances of land. The medieval covenant, *conventio*, was, when we first hear of it, practically equivalent to a lease, and never became a common instrument of miscellaneous contracting, though the old books recognize the possibility of turning it to various uses of which there are examples; nor had it any sensible influence on the later development of the law. On the whole, in the old common law one could do a great deal by deed, but very little without deed. The minor bargains of daily life, so far as they involved mutual credit, were left to the jurisdiction of inferior courts, of the law merchant and—last, not least—of the church.

**Fidei Laesio.**—Popular custom, in all European countries, recognized simpler ways of pledging faith than parchment and seal. A handshake was enough to bind a bargain. Whatever secular law might say, the church said it was an open sin to break plighted faith; a matter, therefore, for spiritual correction—in other words, for compulsion exercised on the defaulter by the bishop's or the

archdeacon's court, armed with the power of excommunication. In this way the ecclesiastical courts acquired much business which was, in fact, as secular as that of a modern county court, with the incident profits. Medieval courts lived by the suitors' fees. What were the king's judges to do? However high they put their claims in the course of the rivalry between church and crown, they could not effectually prohibit the bishop or his official from dealing with matters for which the king's court provided no remedy. Continental jurists had seen their way, starting from the Roman system as it was left by Justinian, to reduce its formalities to a vanishing quantity and to expand their jurisdiction to the full breadth of current usage. English judges could not do this in the 15th century, if they could ever have done so. Nor would simplification of the requisites of a deed, such as has now been introduced in many jurisdictions, have been of much use at a time when only a minority even of well-to-do laymen could write.

There was no principle and no form of action in English law which recognized any general duty of keeping promises. But could not breach of faith by which a party had suffered be treated as some kind of legal wrong? There was a known action of trespass and a known action of deceit, this last of a special kind, mostly for what would now be called abuse of the process of the court; but in the later middle ages it was an admitted remedy for giving a false warranty on a sale of goods. Also there was room for actions "on the case," on facts analogous to those covered by the old writs, though not precisely within their terms. If the king's judges were to capture this important branch of business from the clerical hands which threatened to engross it, the only way was to devise some new form of action on the case. There were signs, moreover, that the court of chancery would not neglect so promising a field if the common-law judges left it open.

**Assumpsit.**—The mere fact of unfulfilled promise was not enough, in the eyes of medieval English lawyers, to give a handle to the law. But injury caused by reliance on another man's undertaking was different. The special undertaking or "assumption" creates a duty which is broken by fraudulent or incompetent mis carriage in the performance. I profess to be a skilled farrier and lame your horse. It is no trespass, because you trusted the horse to me; but it is something like a trespass, and very like a deceit. An action on the case was allowed without much difficulty for such defaults. The next step, and a long one, was to provide for total failure to perform. A builder, instead of doing bad work, does nothing at all within the time agreed upon for completing a house. Can it be said that he has done a wrong? At first the judges felt bound to hold that this was going too far; but suitors anxious to have the benefit of the king's justice persevered, and in the course of the 15th century the new form of action, called *assumpsit* from the statement of the defendant's undertaking on which it was founded, was allowed as a remedy for nonperformance as well as for faulty performance. Being an action for damages and not for a certain amount, it escaped the strict rules of proof which applied to the old action of debt; being in form for a kind of trespass, and thus a privileged appeal to the king to do right for a breach of his peace, it escaped likewise the risk of the defendant clearing himself by oath according to the ancient popular procedure. Hence, as time went on, suitors were emboldened to use *assumpsit* as an alternative for debt, though it had been introduced only for cases where there was no other remedy. By the end of the 16th century they got their way; and it became a settled doctrine that the existence of a debt was enough for the court to presume an undertaking to pay it. The new form of action was made to cover the whole ground of informal contracts, and, by extremely ingenious devices of pleading, developed from the presumption or fiction that a man had promised to pay what he ought, it was extended in time to a great variety of cases where there was in fact no contract at all.

**Consideration.**—The new system gave no new force to gratuitous promises. For it was assumed, as the foundation of the jurisdiction, that the plaintiff had been induced by the defendant's undertaking, and with the defendant's consent, to alter his position for the worse in some way. He had paid or bound himself to pay money, he had parted with goods, he had spent time in labour

or he had foregone some profit or legal right. If he had not committed himself to anything on the strength of the defendant's promise, he had suffered no damage. To sum up the foregoing in modern language, the plaintiff must have given value of some kind, more or less, for the defendant's undertaking. This something given by the promisee and accepted by the promisor in return for his undertaking is what we now call the consideration for the promise. In cases where debt would also lie, it coincides with the old requirement of value received (*quid pro quo*) as a condition of the action of debt being available. But the conception is far wider, for the consideration for a promise need not be anything capable of delivery or possession. It may be money or goods; but it may also be an act or series of acts, further (and this is of the first importance for modern law), it may itself be a promise to pay money or deliver goods, or to do work, or otherwise to act or not to act in some specified way. Again, it need not be anything which is obviously for the promisor's benefit. His acceptance shows that he set some value on it; but in truth the promisee's burden, and not the promisor's benefit, is material. The last and not strictly logical refinement of holding that, when mutual promises are exchanged between parties, each promise (though by itself of no value) is a consideration for the other and makes it binding, was conclusively accepted only in the 17th century. The result was that promises of mere bounty could no more be enforced than before, but any kind of lawful bargain could; and there is no reason to doubt that this was in substance what most men wanted. Ancient popular usage and feeling show little more encouragement than ancient law itself to merely gratuitous alienation or obligations. Also (subject, till quite modern times, to the general rule of common-law procedure that parties could not be their own witnesses, and subject to various modern statutory requirements in various classes of cases), no particular kind of proof was necessary. The necessity of consideration for the validity of simple contracts was unfortunately confused by commentators, almost from the beginning of its history, with the perfectly different rules of the Roman law about *nudum pactum* (a pact made without consideration), which very few English lawyers took the pains to understand.

The doctrine of consideration is in fact peculiar to those jurisdictions where the common law of England is in force, or is the foundation of the received law, or, as in South Africa, has made large encroachments upon it in practice. Substantially similar results are obtained in other modern systems by professing to enforce all deliberate promises, but imposing stricter conditions of proof where the promise is gratuitous.

As obligations embodied in the solemn form of a deed were thereby made enforceable before the doctrine of consideration was known, so they still remain. When a man has by deed declared himself bound, there is no need to look for any bargain or even to ask whether the other party has assented. This rugged fragment of ancient law remains embedded in our elaborate modern structure. Nevertheless, gratuitous promises, even by deed, get only their strict and bare rights. There may be an action upon them, but the powerful remedy of specific performance—often the only one worth having—is denied them. For this is derived from the extraordinary jurisdiction of the chancellor, and the equity administered by the chancellor was not for plaintiffs who could not show substantial merit as well as legal claims. The singular position of promises made by deed is best left out of account in considering the general doctrine of the formation of contracts, and as to interpretation there is no difference. In what follows, therefore, it will be needless, as a rule, to distinguish between "parol" or "simple" contracts, that is, contracts not made by deed, and obligations undertaken by deed.

**Promise and Offer.**—From the conception of a promise being valid only when given in return for something accepted in consideration of the promise, it follows that the giving of the promise and of the consideration must be simultaneous. Words of promise uttered before there is a consideration for them can be no more than an offer; and, on the other hand, the obligation declared in words or inferred from acts and conduct, on the acceptance of a consideration, is fixed at that time and cannot be varied by sub-

sequent declaration, though such declarations may be material as admissions. It was a long while, however, before this consequence was clearly perceived. In the 18th century it was attempted, and for a time with considerable success, to extend the range of enforceable promises without regard to what the principles of the law would bear, in order to satisfy a sense of natural justice. This movement was finally checked as late as 1840, and traces of it remain in certain apparently anomalous rules which are indeed of little practical importance but which private writers, at any rate, cannot safely treat as obsolete. However, the question of "past consideration" is too minute and technical to be pursued here. The general result is that a binding contract is regularly constituted by the acceptance of an offer at the moment it is accepted. It also follows that an offer before acceptance creates no duty of any kind, which is by no means necessarily the case in systems where the English rule of consideration is unknown. The question of what amounts to final acceptance of an offer is, on the other hand, a question ultimately depending on common sense. The rules that an offer is understood to be made only for a reasonable time, according to the nature of the case, and lapses if not accepted in due time; that an expressed revocation of an offer can take effect only if communicated to the other party before he has accepted; that acceptance of an offer must be according to its terms, and a conditional or qualified acceptance is only a new proposal, and the like, stand on general convenience as much as on any technical ground.

**Correspondence.**—Great difficulties have arisen, in other systems as well as in the English, as to the completion of contracts between persons at a distance. There must be some rule, and yet any rule that can be framed must seem arbitrary in some cases. On the whole the modern doctrine is as follows:

The proposer of a contract can prescribe or authorize any mode, or at least any reasonable mode, of acceptance, and if he specifies none he is deemed to authorize the use of any reasonable mode in common use, and especially the post. Acceptance in words is not always required; an offer may be well accepted by an act clearly referable to the proposed agreement and constituting the whole or part of the performance asked for—say the dispatch of goods in answer to an order by post, or the doing of work before spoken; and it seems that in such cases further communication—unless expressly requested—is not necessary as a matter of law, however prudent and desirable it may be. Where a promise and not an act is sought (as where a tradesman writes a letter offering goods for sale on credit), it must be communicated; in the absence of special direction, letter post or telegraph may be used; and, further, the acceptor having done his part when his answer is committed to the post, English courts since 1879 have held, after considerable previous doubt, that any delay or miscarriage in course of post is at the proposer's risk, so that a man may be bound by an acceptance he never received. It is generally thought—though there is no English decision—that, in conformity with this last rule, a revocation by telegraph of an acceptance already posted would be inoperative. Much more elaborate rules are laid down in some continental codes. It seems doubtful whether their complication achieves any gain of substantial justice worth the price. At first sight it looks easy to solve some of the difficulties by admitting an interval during which one party is bound and the other not. But, apart from the risk of starting fresh problems as hard as the old ones, English principles, as above said, require a contract to be concluded between the parties at one point of time, and any exception to this would have to be justified by very strong grounds of expediency. We have already assumed, but it should be specifically stated, that neither offers nor acceptances are confined to communications made in spoken or written words. Acts or signs may and constantly do signify proposal and assent. One does not in terms request a ferryman to put one across the river. Stepping into the boat is an offer to pay the usual fare for being ferried over, and the ferryman accepts it by putting off. This is a very simple case, but the principle is the same in all cases. The term "implied contract," current in this connection, is ambiguous. It sometimes means a contract concluded by acts, not words, of one or both parties, but still a real

agreement; sometimes an obligation imposed by law where there is not any agreement in fact, for which the name "quasi contract" or "constructive contract" is more appropriate and now usual.

**Interpretation.**—The obligation of contract is an obligation created and determined by the will of the parties. Herein is the characteristic difference of contract from all other branches of law. The business of the law, therefore, is to give effect so far as possible to the intention of the parties, and all the rules for interpreting contracts go back to this fundamental principle and are controlled by it. Everyone knows that its application is not always obvious. Parties often express themselves obscurely; still oftener they leave large parts of their intention unexpressed, or (which for the law is the same thing) have not formed any intention at all as to what is to be done in certain events. Thus just as there are situations where the parties have made no express contract, either orally or in writing, so that when one man asks another to do certain work and the other does it, the man who does the work will be entitled to reasonable payment for it, so, too, the courts will sometimes imply the existence of certain terms in a contract that is otherwise express. The courts will not, however, make a contract for the parties: all they will do is infer from the express terms of an agreement and from the circumstances what the intentions of the parties were, and seek to give effect to them. Difficulties of interpretation will often arise where one of the parties contends that a contract has been discharged by impossibility of performance, arguing that a term putting an end to the contract in the circumstances that have arisen ought to be implied. There is a wealth of authorities, not always in agreement with each other, on the doctrine of frustration, but it must be emphasized that it is by no means every unexpected turn of events that will bring it into application. It sometimes used to be said that the subject matter of the contract had to be destroyed. The matter is clearly put in *Chitty on Contracts* (22nd ed., vol. 1, p. 1175, Sweet & Maxwell Ltd.): "Theory of a radical change in the obligation. In view of the decision of the House of Lords in *Davis Contractors* (1956, A.C. 696), *Ltd. v. Fareham U.D.C.*, the proper test for frustration may be formulated as follows: If the literal words of the contract were to be enforced in the changed circumstances, would this involve a significant or radical change from the obligation originally undertaken?" The court cannot add to the contract terms that were not in it originally or take away from them in order to do what is just and reasonable in the circumstances. A rule which can take effect against the judicially known will of the parties is not a rule of construction or interpretation but a positive rule of law. However artificial some rules of construction may seem, this test will always hold. In modern times the courts have avoided laying down new rules of construction, preferring to keep a free hand and to deal with each case on its merits as a whole. It should be observed that the fulfillment of a contract may create a relation between the parties which, once established, is governed by fixed rules of law not variable by the preceding agreement. Marriage is the most conspicuous example of this, and perhaps the only complete one in our modern law.

There are certain rules of evidence which to some extent guide or restrain interpretation. In particular, oral testimony is not allowed to vary the terms of an agreement reduced to writing. This is really in aid of the parties' deliberate intention, for the object of reducing terms to writing is to make them certain. There are apparent exceptions to the rule, of which the most conspicuous is the admission of evidence to show that words were used in a special meaning current in the place or trade in question. But they are reducible, it will be found, to applications (perhaps over-subtle in some cases) of the still more general principles that, before giving legal force to a document, we must know that it is really what it purports to be, and that when we do give effect to it according to its terms we must be sure of what its terms really say. The rules of evidence here spoken of are modern, and have nothing to do with the archaic rule already mentioned as to the effect of a deed.

**Performance.**—Every contracting party is bound to perform his promise according to its terms and, in case of any doubt, in the

sense in which the other party would reasonably understand the promise. Where the performance on one or both sides extends over an appreciable time, continuously or by installments, questions may arise as to the right of either party to refuse or suspend further performance on the ground of some default on the other side. Attempts to lay down hard and fast rules on such questions are now discouraged, the aim of the courts being to give effect to the true substance and intent of the contract in every case. Nor will the court hold one part of the terms deliberately agreed to more or less material than another in modern business dealings. "In the contracts of merchants time is of the essence," as the supreme court of the United States has said. Certain ancient rules restraining the apparent literal effect of common provisions in mortgages and other instruments were in truth controlling rules of policy. New rules of this kind can be made only by legislation. Whether the parties did or did not in fact intend the obligation of a contract to be subject to unexpressed conditions is, however, a possible and not uncommon question of interpretation, as we have noted above. One class of cases giving rise to such questions is that in which performance according to the real intent of the parties is frustrated by some external cause not due to the promisor's own fault. As to promises obviously absurd or impossible from the first, they are unenforceable only on the ground that the parties cannot have seriously meant to create a liability. For precisely the same reason, supported by the general usage and understanding of mankind, common social engagements, though they often fulfill all other requisites of a contract, have never been treated as binding in law. The singular case has actually occurred of parties framing a complete business agreement and adding an "honourable pledge clause" which expressly excluded legal jurisdiction. Here the manifest intention not to create an enforceable obligation prevents the other specific terms, however precise, from creating any.

**Illegality.**—In all matters of contract, as we have said, the ascertained will of the parties prevails. But this means a will both lawful and free. Hence there are limits to the force of the general rule, fixed partly by the law of the land, which is above individual will and interests, and partly by the need of securing good faith and justice between the parties themselves against fraud or misadventure. Agreements cannot be enforced when their performance would involve an offense against the law. There may be legal offense, it must be remembered, not only in acts commonly recognized as criminal, disloyal or immoral, but in the breach or non-observance of positive regulations made by the legislature, or persons having statutory authority, for a variety of purposes. Again, there are cases where an agreement may be made and performed without offending the law, but on grounds of "public policy" it is not thought right that the performance should be a matter of legal obligation, even if the ordinary conditions of an enforceable contract are satisfied. A man may bet, in private at any rate, if he likes, and pay or receive as the event may be; but for many years the winner has had no right of action against the loser. But what is really important under this doctrine of public policy is the confinement of "contracts in restraint of trade" within special limits. In the middle ages and down to modern times there was a strong feeling—not merely an artificial legal doctrine—against monopolies and everything tending to monopoly. Agreements to keep up prices or not to compete were regarded as criminal. Gradually it was found that some kind of limited security against competition must be allowed if such transactions as the sale of a going concern with its good will, or the retirement of partners from a continuing firm, or the employment of confidential servants in matters involving trade secrets, were to be carried on to the satisfaction of the parties. Attempts to lay down fixed rules in these matters were made from time to time, but they were finally discredited by the decision of the house of lords in the *Maxim-Nordenfellt* company's case in 1894. Contracts "in restraint of trade" will now be held valid, provided that they are made for valuable consideration (this even if they are made by deed), do not go beyond what can be thought reasonable for the protection of the interests concerned and are not injurious to the public. All that remains of the old rules in England is the neces-

sity of valuable consideration, whatever be the form of the contract, and a strong presumption—but not an absolute rule of law—that an unqualified agreement not to carry on a particular business is not reasonable.

The Restrictive Trade Practices act, 1956, which, among other things, established the restrictive practices court, empowered that court to declare contrary to the public interest any agreements, as defined in sec. 6 of the act, under which restrictions are accepted by the parties in respect of prices, the application of any process of manufacture to goods, the terms or conditions of supply, and a number of other matters. Under sec. 21, such agreements are presumed to be against the public interest unless the court recognizes the existence of certain circumstances set out in the section, such as that the removal of the restriction would deny to the public as purchasers, consumers or users of any goods other specific and substantial benefits or advantages enjoyed or likely to be enjoyed by them as such, whether by virtue of the restriction itself or of any arrangements or operations resulting therefrom. If the court declares restrictions under such an agreement to be contrary to the public interest, the agreement will, by virtue of sec. 20, be void in respect of those restrictions. Sections 24-27 of the act prohibit agreements concerning the collective enforcement of conditions as to resale prices, but individual enforcement may be permitted even, in certain circumstances, against a person who was not a party to the original sale.

**Fraud.**—Where there is no reason in the nature of the contract for not enforcing it, the consent of a contracting party may still not be binding on him because it was not given with due knowledge, or, if he is in a relation of dependence to the other party, with independent judgment. Inducing a man by deceit to enter into a contract may always be treated by the deceived party as a ground for avoiding his obligation if he does so within a reasonable time after discovering the truth and, in particular, before any innocent third person has acquired rights for value on the faith of the contract. (See **FRAUD**.) Coercion would be treated on principle in the same way as fraud, but such cases hardly occur in modern times. There is a kind of moral domination, however, which our courts watch with the utmost jealousy and repress under the name of "undue influence" when it is used to obtain pecuniary advantage. Persons in a position of legal or practical authority—guardians, confidential advisers, spiritual directors and the like—must not abuse their authority for selfish ends. They are not forbidden to take benefits from those who depend on them or put their trust in them; but if they do, and the givers repent of their bounty, the whole burden of proof is on the takers to show that the gift was in the first instance made freely and with understanding. Large voluntary gifts or beneficial contracts, outside the limits within which natural affection and common practice justify them, are indeed not encouraged in any system of civilized law. Professional moneylenders were formerly checked by the usury law; after those laws were repealed in 1854, courts and juries showed a certain astuteness in applying the rules of law as to fraud and undue influence—the latter with certain special features—to transactions with needy "expectant heirs" and other improvident persons which seem on the whole unconscionable. The Money-Lenders act of 1900 and subsequent amendments have fixed and (as finally interpreted by the house of lords) also sharpened these developments. In the case of both fraud and undue influence, the person entitled to avoid a contract may, if so advised, ratify it afterward; and ratification, if made with full knowledge and free judgment, is irrevocable. A contract made with a person deprived by unsound mind or intoxication of the capacity to form a rational judgment is on the same footing as a contract obtained by fraud, if the want of capacity is apparent to the other party.

**Misrepresentation.**—There are many cases in which a statement made by one party to the other about a material fact will enable the other to avoid the contract if he has relied on it and it was in fact untrue, though it may have been made at the time with honest belief in its truth. This is so wherever, according to the common course of business, it is one party's business to know the facts and the other practically must, or reasonably may, take

the facts from him. In some classes of cases even inadvertent omission to disclose any material fact is treated as a misrepresentation. Contracts of insurance are the most important; here the insurer very seldom has the means of making any effective inquiry of his own. Misdescription of real property on a sale, without fraud, may according to its importance be a matter for compensation or for setting aside the contract. Promoters of companies are under special duties as to good faith and disclosure which have been worked out at great length in the modern decisions. But company law has become so complex within the present generation that, so far from throwing much light on larger principles, it is hardly intelligible without some previous grasp of them.

Mistake is said to be a ground for avoiding contracts, and there are cases which it is practically convenient to group under this head. On principle they seem to be mostly reducible to failure of the acceptance to correspond with the offer, or absence of any real consideration for the promise. In such cases, whether there be fraud or not, no contract is ever formed, and therefore there is nothing which can be ratified—a distinction which may have important effects. Relief against mistake is given where parties who have really agreed, or rather their advisers, fail to express their intention correctly. Here, if the original true intention is fully proved—as to which the court is rightly cautious—the faulty document can be judicially rectified.

**Disability.**—By the common law an infant (*i.e.*, a person less than 21 years old) was bound by contracts made for "necessaries," *i.e.*, such commodities as a jury holds, and the court thinks they may reasonably hold, suitable and required for the person's condition; also by contracts otherwise clearly for his benefit; all other contracts he might confirm or avoid after coming of age. An extremely ill-drawn act of 1874 absolutely deprived infants of the power of contracting loans, contracting for the supply of goods other than necessaries, and stating an account so as to bind themselves; it also disabled them from binding themselves by ratification. The liability for necessaries was declared by legislative authority in the Sale of Goods act, 1893; the modern doctrine is that it is in no case a true liability on contract. There is an obligation imposed by law to pay, not the agreed price, but a reasonable price. Practically, people who give credit to an infant do so at their peril, except in cases of obvious urgency.

Married women were incapable by the common law of contracting in their own names. They can now hold separate property and can bind themselves to the extent of that property—not personally—by contract. The law before the Married Women's Property acts (1882 and 1893, and earlier acts now superseded and repealed) was a very peculiar creature of the court of chancery; the cases in which it is necessary to go back to it are, of course, very few. But a married woman can still be restrained from anticipating the income of her separate property, and the restriction is still commonly inserted in marriage settlements. (See also WOMEN, LEGAL POSITION OF.)

There is a great deal of philosophical interest about the nature and capacities of corporations, but for modern practical purposes it may be said that the legal powers of British corporations are directly or indirectly determined by acts of parliament. For companies under the Companies acts the controlling instrument or written constitution is the memorandum of association. Company draftsmen, taught by experience, nowadays frame this in the most comprehensive terms. Questions of either personal or corporate disability are less frequent than they were. In any case they stand apart from the general principles of our law of contract.

**Contract and Property.**—The rights created by contract are personal rights against the promisors and their legal representatives, and therefore different in kind from the rights of ownership and the like which are available against all the world. Nevertheless, they may be and very commonly are capable of pecuniary estimation and estimated as part of a man's assets. Book debts are the most obvious example. Such rights are property in the larger sense: they are in modern law transmissible and alienable, unless the contract is of a kind implying personal confidence or a contrary intention is otherwise shown. The rights created by negotiable instruments are an important and unique species of

property, being not only exchangeable but the very staple of commercial currency. Contract and conveyance, again, are distinct in their nature, and sharply distinguished in the classical Roman law. But in the common law, property in goods is transferred by a complete contract of sale without any further act, and under the French civil code and systems which have followed it a like rule applies not only to movables but to immovables. In English law, procuring a man to break his contract is a civil wrong against the other contracting party, subject to exceptions which are still not clearly defined. (F. Po.; W. T. Ws.)

## MODERN ANGLO-AMERICAN LAW

**Forms of Contract.**—Though a contract originates in offer and acceptance, these, as stated above, need not be express or explicit. A public bus, for example, may stop for a passenger, who boards the bus and drops a coin in the fare box; a contract has been made by which the proprietor of the bus promises to transport the passenger to any station on the bus's route. Again, someone may enter a store where he carries a charge account, pick up an article from the counter and show it to a clerk; if the clerk nods his head and the customer puts the article in his pocket and walks out, a contract has been made by which the customer is bound to pay a reasonable (or marked) price for the article, though no word has been spoken on either side. The term "implied-in-fact" has been applied to this type of contract.

Contracts involving land, goods or large-scale construction are frequently the result of higgling or negotiating about terms. This type of agreement may be oral, or reduced to writing and signed by the parties, or it may be made by an interchange of letters. Such contracts are said to be express.

The standardized contract has become increasingly important in recent years. Firms engaged in particular lines of business have found it feasible and economical to prepare and print their own contract forms in advance. This practice makes it possible for unskilled clerks and salesmen, in negotiating contracts, to use the knowledge and training of the executives and lawyers of the firm. The procedure simplifies interpretation and the settlement of disputes. The standardized contract, while performing a useful economic function, has introduced new legal problems. Someone dealing with a firm that uses a standard form has little opportunity to negotiate or to object to terms; his only choice is to accept or reject the proposal in its entirety. Faced with this situation he frequently does not read more than the main items of the contract. Has he agreed to the terms of the document in any real sense? The courts hold that he should have read it, so that whether he has or not, he is usually bound by its terms. If, however, the court believes the parties to be unequal in bargaining power or if some of the terms are harsh or uncouth (especially if they are in small type), many courts will refuse to enforce the agreement; and if a term is ambiguous, the doubt will be resolved against the party who drafted the instrument. In many areas of business such as public utilities and insurance, the legislature has intervened to prescribe contract terms. It is evident that the standardized contract and the state regulation of contract forms have substantially restricted the scope of the doctrine of the freedom of contract.

**Promissory Estoppel.**—An important alternative to the requirement of consideration is that if a promisee foreseeably has detrimentally relied upon a promise, though his detriment was not bargained for, the promise is binding. The principle (called promissory estoppel) has been generally recognized in the United States and has been recommended in England by the English Law Revision committee (1937), but parliament has taken no action upon it. The principle has been most frequently applied to gratuitous bailments, charitable subscriptions and gratuitous promises to convey land, but has recently been extended to a number of other cases.

**Contract Under Seal.**—A type of contract that does not necessarily originate in bargain is one under seal, variously called a covenant, bond, obligation, specialty or deed. The seal, originally a piece of wax, with the covenantor's identifying mark upon it, may now consist of a mark or scroll or simply "seal" written or

printed upon the document. By the common law, a promise under seal (a covenant) is binding though the covenantor receives no consideration. Thus the seal is a device by which a gratuitous promise can be made binding. In a majority of states of the U.S., the effectiveness of the seal upon contracts has been abolished. In some states it creates a rebuttable presumption of consideration. In other states and in England the seal is still recognized, and its use is required on contracts made by corporations.

**The Statute of Frauds.**—The fourth section of the Statute of Frauds, enacted by the British parliament in 1677 and re-enacted in whole or in part, in one form or another, in nearly all the U.S. states, provides that the following five kinds of contracts shall be unenforceable unless evidenced by a signed writing: (1) the promise of an executor or administrator to pay a debt of the decedent; (2) a promise to pay the debt of another person; (3) a promise in consideration of marriage; (4) a contract for the sale of land; and (5) a contract not to be performed within a year. By the 17th section of the same statute, a sixth type of contract, one for the sale of goods of the price of £10 or more, is made unenforceable unless the buyer accepts and receives a part of the goods, makes a part payment, or unless the contract is evidenced by a signed writing.

In 1954 parliament repealed these sections of the statute, except the parts covering contracts to pay the debts of another and contracts for the sale of land. No U.S. state has followed suit. While the statute has undoubtedly prevented the enforcement of many fabricated contracts, it has also been the means by which dishonest persons have evaded their promises. Whether the statute has caused more frauds than it has prevented is a much debated question.

**Third-Party Beneficiaries.**—In England a contract is looked upon as a purely personal transaction. Hence the view is usually taken that a person cannot acquire a right on a contract to which he is not a party. However, some exceptions to the rule have been enacted by statute, and the courts have developed others. Though the Law Revision committee has recommended the general recognition of third-party-contract rights, the recommendation has not been adopted.

In the United States, nearly all jurisdictions follow the view that two persons can make a contract for the benefit of a third person. When such an intent on their part is manifest, the third party acquires a right by virtue of the agreement even though he is not a direct party to it and furnishes no consideration. The right created by the contract may be a gift to the third party, in which case he is called a donee beneficiary; or the purpose of the contract may be to pay a debt owed by one of the contracting parties to the third party, in which case he is a creditor beneficiary.

An illustration of a donee-beneficiary contract is a life insurance policy on the life of A procured by him from B and made payable to A's wife C. An example of a creditor-beneficiary contract is one in which A sells his business to B and, as part consideration, B promises to pay A's debt to C. In each of these cases, C may maintain an action against B on his promise made to A.

**Assignments.**—Since contracts, unlike property interests, were considered strictly personal at common law, the courts from early times held that it was not permissible for a contract right to be transferred or assigned. However, courts of equity became dissatisfied with this rule and began to break it down. Courts of law took over the law merchant or mercantile law, which recognized the transferability of bills of exchange. This recognition was later extended to other money claims such as ordinary debts and book accounts and finally, with the aid of statute, to other contract rights not involving strict personal performance or confidence. In mid-20th century the general rule both in Great Britain and the United States, with few exceptions, was that contract rights are assignable.

Most states of the U.S. follow the rule that the assignment is complete as of its date, but England and some states take the view that the assignment is not complete until notice is given to the obligor.

A basic principle in the law of assignment is that an assignee takes subject to equities and defenses, whether or not he is a pur-

chaser in good faith. This means that if there are any defects in the right assigned, if it is subject to conditions or if at the time of notice of the assignment the obligor has a counterright against the assignor, these facts can be used against the assignee as a defense or as a means of reducing the assigned claim. In this respect the assignment of a simple contract right is to be distinguished from the transfer (negotiation) of a bill of exchange, where the transferee, if he is a good-faith purchaser, takes the instrument free of personal defenses and equities. (See COMMERCIAL PAPER.)

**Dependent Promises.**—Under the early common law, in an action on a bilateral contract, the plaintiff could recover a judgment whether or not he himself had performed his part of the bargain. The plaintiff's own nonperformance did not excuse the defendant. The respective promises were said to be independent, and each party had his remedy against the other for breach of promise. In the modern law of both England and the United States, however, if a material part of the plaintiff's performance is to be rendered prior to or simultaneously with that of the defendant's, the plaintiff's failure to perform or to tender performance excuses the defendant. The defendant's promise is said to be dependent; performance by the plaintiff is a condition. If the promises on both sides are capable of simultaneous performance they are mutually dependent, neither party being able to recover from the other without himself performing or offering to perform.

A contractual promise also may be conditional upon agreed acts or events. For example, an owner's duty to pay a contractor for constructing a building may be conditional upon the contractor's furnishing an architect's certificate of satisfactory work. Likewise, a condition may be constructed or implied by the court on the basis of policy or equity. If, for example, a promise is such that it requires co-operative action by the promisee in its performance, co-operation is a condition even though it is not so stated in the contract. If performance on one side can be rendered instantaneously (like paying money) but performance on the other side requires an appreciably longer time (like plowing a garden), it is implied that the act requiring the longer time is a condition precedent to the duty to perform on the other side.

**Impossibility and Frustration.**—Unless a promisor assumes the risk, supervening impossibility of performing his promise, due to a fortuitous event, excuses him from his duty. In a well-known case, D agreed to let a music hall to P for four days for a grand concert, for which P was to pay £400. Before the time for the concert, the music hall was accidentally destroyed by fire. It was held that D was excused from his duty by reason of impossibility.

Likewise, though performance is possible, if the value of the performance is almost totally destroyed by a supervening event, the promisor is excused. Thus, D agreed to hire from P for £75 a flat in Pall Mall during the days of June 26 and 27, 1902, the dates on which the coronation procession of Edward VII was to pass along that street. When illness of the king caused a postponement of the procession, it was held that D was excused from his duty to pay the rent. Frustration of purpose had destroyed the value of P's performance.

Courts differ in their rationalization of the doctrines of impossibility and frustration. The best explanation of the results seems to be that the courts believe it is inequitable to hold a person to a contract where, because of a fortuitous event, he gets nothing for his promise.

**Discharge.**—Discharge pertains to the termination of the contractual relation. Only a few of the many methods of discharge can be considered here. Complete performance by both parties is the usual method. If the contract is wholly or partly unperformed on both sides, the contract can be terminated by simple agreement, the surrender by each party of his right serving as consideration for the other's surrender. If the contract is fully performed by one party only, the other party can be discharged by obtaining a valid release. For a release to be valid it must be under seal (where seals are still recognized), or in writing (where statutes so provide), or be supported by consideration. Such a contract also may be terminated by accord and satisfaction. The accord, which states the terms of the discharge, may itself constitute a contract made in substitution of the original claim, in which

case it is an accord and satisfaction. Or the new agreement may require that it be performed to constitute a discharge of the original claim, in which case the new agreement is an accord. Still another method for discharging this type of claim is for the creditor to agree to accept a new debtor in place of the original one. This is called a novation.

**Remedies.**—In cases where compensatory damages would be inadequate, the equitable remedy of specific performance is sometimes available to a party injured by breach of contract. In granting this remedy, the court orders the defendant to do the specific act he had agreed to do. In practice the remedy is usually limited to contracts for the sale of land and unique chattels.

The usual remedy for breach of contract is compensatory damages. Penal or vindictive damages are rarely awarded. The rule is that the plaintiff is entitled to recover such damages as were or reasonably should have been foreseen at the time the contract was made. In most cases this means that the plaintiff is entitled to be placed in the economic position that he would have occupied had the contract been performed. (See also DAMAGES.)

**CONTRACT BRIDGE:** see BRIDGE.

**CONTRACT LABOUR,** a term to describe workers whose freedom is restricted by the terms of a contractual relation and by laws that make such arrangements permissible and enforceable. In American colonial times, indentured servants were a form of contract labour; in the middle and later 19th century, Chinese and Indian labourers, commonly called coolies, moved great distances under contractual arrangements. Deception, kidnapping and coercion were widely used as means of obtaining control of defenseless persons, usually unskilled and poorly educated adult males.

The contractual terms usually reflected the disadvantageous position of the labourer, often to the extent of harshness approaching slavery. Although coercion and harshness no longer prevail, the concept of contract labour continues to imply undesirable attributes of compulsion and cheapness, and hence of unfairness to the labourers directly involved and also to others in the labour force.

**Colonial Indenture.**—North American indentured labour began with the founding of the colonies and existed concurrently with free labour and slavery until the American Revolution. Its subjects were males and females of western European and mainly British origin. The terms of indenture were harsh to favourable, depending upon the strength of the individual's position and the preferences of his master. The harshest terms and the longest indentures were imposed upon criminals whose death sentences (often for political offenses and numerous crimes now regarded as misdemeanours) were commutable upon entry into colonial indentures.

At the other extreme, those able to negotiate the terms of indenture were able to obtain contracts generally patterned after English apprenticeship customs and were usually free after five to seven years of service. Colonial laws gave some protection to the indentured servant but also sanctioned and enforced performance of the contract whether oral or written.

The indenture of Chinese and Indians also was associated with colonial developments but occurred later, following the abolition of slavery in areas other than the American colonies. Indian emigrant labourers were brought into British, French and Netherlands African colonies and also into Ceylon, Malaya and the Caribbean. Chinese labourers served in many of these areas and also in Peru, Western Samoa, New Zealand and Hawaii. The Chinese, Japanese and Hindustani workers who came to California in the

latter 19th century were commonly regarded as coolies, but they were mainly free immigrants, some of whom had completed or escaped from indenture contracts. Their numbers included remigrants from the indentures that were intended to serve the sugar plantations of Hawaii. Although Asian indenture was not free of kidnap, decoy and fraud, it was basically a noncompulsory system to the extent that the governments of China and India were able to protect the interests of their nationals by legislation and negotiation. Poverty in the home country was the foundation of Asiatic indenture. In contrast, American colonial indenture, though founded partly on poverty, was also fed by a harsh penal code characterized by political and religious intolerance.

Aside from other stipulations regarding such matters as repayment of transportation, wages and housing, the essence of the contract labourer's obligation was his surrender of freedom, for a specified period, to quit his work and his master (employer). The acceptance and imposition of such restrictions were in accord with European apprenticeship practices and were sanctioned by the prevailing master-and-servant legislation. Not until the English Employers and Workmen act (1875) did the master-servant practice give way to the concept and practice of free, impersonal labour relations and the reciprocal rights and obligations of employers and employees.

**U.S. Legislation.**—The periods of large-scale immigration to the United States offered many opportunities for practices that were momentarily advantageous to the emigrant but abusive of more liberal principles. Under various forms of assisted immigration, buttressed by the immigrants' language and financial disabilities, many nationality groups rendered temporary services in such major U.S. industries as railroads and mines under conditions that were not legally enforceable. In 1864 the United States congress, under the pressure of the labour shortage resulting from the Civil War, undertook to validate alien labour contracts in an effort to promote greater importation of alien labour. The act provided that contracts pledging the repayment of expenses of emigration from wages for a 12-month term were valid and enforceable in the federal, state and territorial courts.

Fearing that the U.S. labour market would be flooded by cheap labour, congress repealed the act four years later. Specific prohibitions against the practice of encouraging or assisting labourers of foreign countries to emigrate to the United States were not enacted, however, until congress passed the Contract Labour law of 1885, which forbade the entry of any person, other than a skilled or professional worker, who had previously made a labour contract.

Notwithstanding the 1885 law and subsequent legislation against contract labour, some forms of it continued in the United States. These are more closely related to the coolie system than to European master-servant practices. Twentieth-century labour contracting—which exists in significant volume only in the United States—has its foundation in two factors, both characteristic of the Asian indenture: (1) the sharply contrasting differences in employment opportunities between nations; and (2) the peculiar sanctions that law permits against nonimmigrant aliens.

Although the U.S. immigration law of 1917 continued the 1885 prohibition of contract labour, it also contained a proviso authorizing "the commissioner of immigration and naturalization, with the approval of the attorney general, . . . to control and regulate the admission and return of otherwise inadmissible aliens applying for temporary admission." Under this proviso, a limited importation of Mexican unskilled labour was permitted during World War I. The proviso then remained dormant until World War II, when it was extensively invoked, especially with respect to Mexican workers for agriculture and the maintenance of railway track. Nonagricultural importation was discontinued in 1945, but the importation of alien farm workers continued. Until the Immigration and Nationality act of 1952, the authority utilized to sanction such importation was the ninth proviso of the 1917 law. The 1952 law permits temporary entry of nonimmigrant alien labourers, "if unemployed persons capable of performing such service or labor cannot be found in this country . . . after consultation with appropriate agencies of the Government, upon petition of the importing

employer." The last phrase is crucial, for it specifies that the initiative is governed by employer interest. Importation actions under this authority have been initiated by farm employers only.

After 1952, total nonimmigrant alien entries of farm labourers from Mexico, the Caribbean countries and Japan were approximately 500,000 annually. For Mexican labour, the importation was facilitated and regulated by an intergovernmental executive agreement (not a treaty) and by public law 78 of 1951. Entries are under short-term contracts that are standardized for each nationality group. Governments of the labour-supplying countries negotiate or supervise the terms of these contracts. Public law 78 (relating to Mexico only and a temporary measure that has been extended several times) specifies that importations shall be approved only if domestic workers are not available and such importations "will not adversely affect the wages and working conditions of domestic agricultural workers."

These contractual importations of nonimmigrant aliens are regarded with general favour in the supplying countries but are the subject of intense controversy in the United States. Farm employers allege the insufficiency of domestic labour and their dependency on continued alien importation as a supplemental supply source. However, only a small proportion of U.S. farmers utilize alien labour. Antagonists of the contract alien program argue that, contrary to the requirements of the law, the importations adversely affect the wages and conditions of domestic farm workers, who, even without the competition of alien labour, are one of the least protected segments of the national work force.

See Louise E. Howard, *Labour in Agriculture*, Royal Institute of International Affairs (1935); U.S. Department of Labor, *Farm Labor Fact Book* (1959).

**CONTRADICTION, LAW OF:** see THOUGHT, LAWS OF.

**CONTRALTO**, or alto, the term for the lowest variety of the female voice, below soprano and mezzo-soprano, and in the four-part choir the second highest voice.

**CONTRAPUNTAL FORM:** see COUNTERPOINT.

**CONTREDANSE**, a dance derived from the English country dance (*q.v.*), whence also it takes its name, which enjoyed much popularity both in France and Germany during the 18th century and later. Although the derivation of the name has been disputed, it is confirmed by the character of the dance itself, which had obvious features in common with those of its English original. The name was also applied to the music for such dances, of which Beethoven and Mozart both left examples.

**CONTRERAS**, a hamlet about 8 mi. S.W. of Mexico City, near which, on Aug. 19–20, 1847, the army of Maj. Gen. Winfield Scott opened the final campaign of the war between the United States and Mexico. Pop. (1960) 12,516. Scott's army had crossed the mountain barrier east of the capital on Aug. 10 and entered the valley of Mexico. After reconnoitering possible approaches to Mexico City, Scott decided to move south of Lake Chalco and occupy a position on the Acapulco road, which entered the city from the south. Finding this road blocked by units of Gen. A. L. de Santa Anna's army, Scott planned a flanking movement to the west across lava beds known locally as the pedregal. This was anticipated by General Valencia, who occupied the hill of Padierna, just north of Contreras, with 4,000 men. Advance units of Scott's flanking force established contact with Valencia's men on the afternoon of Aug. 19. During the following night, they passed to the north and west around Padierna and at daylight attacked the defenders from the rear. After an engagement lasting less than 20 minutes, Valencia's men fled in disorder, leaving behind a considerable number of cannon and prisoners. By this success, Scott gained control of several roads leading to Mexico City. Before advancing on the capital, however, he turned aside to attack the forces on the Acapulco road, in the battle of Churubusco (*q.v.*), on the afternoon of Aug. 20. See also MEXICAN WAR.

**CONTROLLING INTEREST:** see CORPORATION.

**CONTROL SYSTEMS.** In the most general sense, a control system is any means, natural or artificial, by which a variable quantity or a set of variable quantities is caused to conform, more

or less accurately, to some prescribed norm. A familiar example of an artificial control system is a governor for maintaining the speed of an engine at a desired constant value. Another example of a similar kind is a thermostatic heating system for regulating room temperature. In many cases control systems are not designed to hold the values of the controlled quantities constant but rather to cause those values to vary in prescribed ways. The bodies of living organisms contain numerous natural control systems. These ensure the proper involuntary functioning of organs and the proper performance of voluntary actions. So general is the concept of a control system that it has even been possible to use it, more or less successfully, in the discussion of some psychological and sociological phenomena. However, the control systems which lend themselves best to clear and concise discussion are the artificial ones used in modern technology. It is to these that the remainder of this article is devoted.

Although the use of simple control systems, such as the governor, has a long history, early developments were slow and empirical. It was not until about the time of World War II that the systematic design and use of control systems came to be recognized as an important branch of engineering. Today control systems are used in abundance for a great variety of purposes, including the regulation of manufacturing processes and the guidance of the motions of machines (*e.g.*, the autopilots used on airplanes). An extensive theory relating to control systems and their applications has been developed.

This theory, which has been termed cybernetics (from the Greek word for steersman), formulates the requirements which control systems, intended for different purposes, should satisfy. It provides methods for the theoretical design of various kinds of control systems, and it furnishes criteria for judging the performances of control systems in actual operation. The content of the theory consists essentially of portions of various familiar mathematical and physical subjects (*e.g.* dynamics, theory of differential equations and probability theory), this material being unified and reformulated for application to the novel problems associated with control systems.

The interactions among the constituent parts of a control system, and the ensuing transmission of physical (or other) effects from one part to another, can be advantageously regarded as a flow of signals through the system.

Thus it comes about that some of the basic notions and principles of cybernetics also play important parts in "information theory" (*q.v.*). Just how closely the two theories are related depends on how broadly the somewhat elastic term "information theory" is interpreted.

With few and relatively unimportant exceptions, all modern control systems have two fundamental characteristics in common. These can be described, in somewhat oversimplified form, as follows: (1) The value of the controlled quantity is varied by a motor (this word being used in a generalized sense) which draws its power from a local source rather than from an incoming signal. Thus there is available a large amount of power to effect necessary variations of the controlled quantity and to ensure that the operations of varying the controlled quantity do not load and distort the signals on which the accuracy of the control depends. (2) The rate at which energy is fed to the motor, in order to effect variations in the value of the controlled quantity, is determined more or less directly by the difference between the actual and desired values of the controlled quantity. Thus, for example, in the case of a thermostatic heating system, the supply of fuel to the furnace is determined by whether the actual temperature is higher or lower than the desired temperature. (Contrast this with a conceivable, but impractical, heating system in which fuel is fed to the furnace according to a schedule which is established a priori, and is independent of the actual temperature achieved.)

A control system possessing these fundamental characteristics is called a closed-cycle control system, or sometimes a servomechanism. Open-cycle control systems are of comparatively little importance.

It can be said briefly that a closed-cycle control system functions by means of a controlled release of energy from a local

source. This being the case, it is evident that unless the system is carefully designed, energy may be released from the source more rapidly than is necessary to effect the required adjustments of the value of the controlled quantity. When such an excessive release of energy occurs, the control system is unstable; and the controlled quantity, instead of settling down to the desired value, typically goes into a state in which it oscillates to and fro through a large range of values. Since an instability in a control system would defeat the very purpose of the system, the primary problem in its design is that of ensuring that the system is stable. The way in which this problem is attacked and solved depends somewhat on the particular kind of control system that is under consideration.

**Linear Control Systems.**—The control systems with the most familiar theoretical basis are those governed by systems of equations of motion which are linear differential equations with constant coefficients. General dynamical theory shows that such a linear control system has associated with it a certain characteristic equation,  $F(p) = 0$ , which can be written explicitly when the physical structure of the system is specified. The general theory shows also that whether or not the system is stable depends on the nature of the roots of this equation. Specifically, the system is stable in a strong sense if, and only if, all of the roots of the characteristic equation have negative real parts. Mathematical analysis affords various criteria for determining whether or not all of the roots of an algebraic equation have negative real parts.

Any of these criteria serves to determine whether or not a proposed design will result in a stable control system. One criterion, known as Nyquist's stability criterion, is particularly useful since it frequently suggests structural modifications which will stabilize an unstable system or improve the stability of an inadequately stable one. In effect, this criterion is merely a reformulation, in terms which are convenient for the purposes of cybernetics, of a theorem of A. L. Cauchy stating that the number of roots of an algebraic equation  $F(p) = 0$  within a closed curve  $C$  in the complex plane is  $(2\pi)^{-1}$  times the net variation of the argument of  $F(p)$  as the point  $p$  describes  $C$  in the positive sense.

The stability problem for other linear control systems (such as systems having equations of motion which are linear difference equations or linear difference-differential equations) can be solved by appropriate modifications of the methods just considered. Also, these methods, with appropriate modifications and reservations, are frequently used in cases of nonlinear systems.

Once the stability of a control system has been assured, the designer must consider a number of important secondary problems. These relate to the speed and accuracy of the system, and to its insensitivity to accidental disturbances (noise). Essentially, these are problems which arise in connection with most, if not all, communication systems.

At least in the case of linear systems, satisfactory solutions are provided by the methods and results of modern communication engineering. For example,  $x(t)$ , the desired value of the controlled quantity, may be regarded as an input signal and  $y(t)$ , the actual value of the controlled quantity, as the corresponding output signal. From this point of view a well-designed linear control system is usually a low-pass filter, having a certain cut-off frequency. One of the basic results of communication engineering (or information theory) shows that the speed of the system, defined in any one of several possible ways, is proportional to this cut-off frequency.

**Nonlinear Control Systems.**—Nonlinearities may be present in a control system as incidental imperfections in a system which is designed to be essentially linear, or they may be present intentionally as a part of the fundamental design of the system. In the first of these cases the effects of the nonlinearities can usually be neglected or dealt with by means of the appropriate methods of perturbation theory. However, in the second case, the one in which nonlinearities are introduced intentionally, a theory differing radically from the theory of any linear system is required. Because of the great variety of nonlinearities which can be employed in different applications, little exists in the way of a practically useful general theory. Most of the theory of nonlinear control systems consists of a collection of partial theories dealing with various more or less particular situations.

Among the more important of the control systems possessing intentionally introduced nonlinearities is the so-called "on-off" system. Such a control system is characterized by the fact that if the desired value of the controlled quantity exceeds the actual, the motor exerts a certain maximum force to increase the actual value, while if the actual value exceeds the desired value, the motor exerts a certain maximum force to decrease the actual value. Thus the motor admits of only three states: the state in which it exerts no force, the state in which it exerts a positive force of a fixed magnitude and the state in which it exerts a negative force of a fixed magnitude. The functional relation between the force and the error (i.e., the difference between the actual and desired values of the controlled quantity) is nonlinear. An on-off control system can be constructed with parts that are simple, rugged and reliable. Hence such systems, although they do not afford the precision of control that is obtainable from some of the other systems, have a wide field of usefulness. They are particularly helpful in situations where the control involves the motions of large masses and the expenditure of large amounts of power.

In the usual on-off control systems the only important nonlinearities are the nonlinear relations between the forces and the errors defined above. Hence, as long as the error remains of one sign, such a system is equivalent to a linear system; but the equivalent linear system changes with the sign of the error. Such a system belongs to a class of nonlinear systems called piecewise-linear. Since a nonlinear control system can usually be approximated by a piecewise-linear system, and since the piecewise-linear systems are relatively easy to study, the investigation of these systems forms a natural approach to the study of nonlinear control systems in general. See also CYBERNETICS; SERVOMECHANISM.

Phillips (eds.), *Theory of Servomechanisms* (1947), a standard treatise for engineers. Linear systems are emphasized. I. Flügge-Lotz, *Discontinuous Automatic Control* (1953), a monograph giving a detailed and extensive discussion of on-off and other piecewise-linear control systems. (L. A. MACC.)

**CONVECTION**, the transference of a mass of fluid against the force of gravity. If a fluid is heated from below, the lower part of it becomes less dense than that above and rises while the latter falls to take its place. This motion involves an upward transfer of heat and is quite distinct from conduction, whereby heat is transferred in all directions equally by the vibrations of the molecules (for isotropic media), and from radiation, which is transmitted through space without the aid of a material medium.

In the atmosphere, convection is the most important means by which heat is transferred, the absorption of radiation being small and the heat conduction being negligible by comparison. See *HEAT: Transference of Heat*; see also references under "Convection" in the Index volume. (H. R. B.)

**CONVENT**, the body of persons associated together in a monastery, whose official designation is "the abbot (or prior, etc.) and convent" of the place in question (Lat. *conventus*, from *convenire*, "to come together"). The modern popular use of the word for a house of nuns, as distinct from a monastery or house of male religious, is inaccurate: all houses of religious communities are monasteries, irrespective of the sex of the convent that inhabits them, and the term convent is equally free from such limitations. See MONASTERY.

**CONVENTION, NATIONAL (U.S.):** see NATIONAL CONVENTION.

**CONVERSE, FREDERICK SHEPHERD** (1871–1940), U.S. composer whose essentially romantic music is coloured with some impressionistic touches, was born in Newton, Mass., Jan. 5, 1871. He studied music at Harvard (1889–93) and later with G. W. Chadwick in Boston and J. G. von Rheinberger in Munich. He was on the staff at Harvard university (1901–07) and at the New England Conservatory of Music (1899–1901 and 1930–38).

Converse attracted national attention with his "romantic grand opera" in one act, *The Pipe of Desire* (1906), the first opera by an American to be given by the Metropolitan Opera company (New

York, March 18, 1910). His symphonic fantasy *Flüvier Ten Million* (1927), written to celebrate the manufacture of the 10,000,000th Ford automobile and scored in an appropriately modernistic manner, aroused momentary interest as an example of "machine music." Converse composed six symphonies; the symphonic poems *The Festival of Pan* (1900), *Endymion's Narrative* (1901), *The Mystic Trumpeter* (1904), *Ormazd* (1911); chamber music, and many songs. He died in Westwood, Mass., June 8, 1940. (N. Sv.)

### CONVERSION (IN LOGIC AND MATHEMATICS).

For the converse of a categorical proposition, and for conversion as an immediate inference, see LOGIC, and the section on Aristotle in LOGIC, HISTORY OF.

In mathematics the term *converse* is used for the proposition obtained by the transformation of  $AB \supset C$  into  $AC \supset B$ , or of  $(x_1)(x_2) \dots (x_n) \cdot AB \supset C$  into  $(x_1)(x_2) \dots (x_n) \cdot AC \supset B$ , where  $x_1, x_2, \dots, x_n$  are variables of any kinds; and where  $A, B, C$  are propositional forms, of which some may be themselves conjunctions, or  $A$  may as a special case be absent. (For explanation of the notation and terminology, see LOGIC.) This may in some instances be reduced to the simple converse of an  $A$  proposition in the sense of traditional logic—for example: *Every equilateral triangle is [an] equiangular [triangle]*, and conversely, *every equiangular triangle is [an] equilateral [triangle]*. But such a reduction becomes either impossible or very artificial in cases like that of Euclid I 25 and its converse (*If two sides of a triangle are equal, respectively, to two sides of another triangle, and the third side of the first is greater than the third side of the second, then the angle opposite the third side of the first triangle is greater than that opposite the third side of the second triangle*, and conversely, *if two sides of a triangle are equal, respectively, to two sides of another triangle, and the angle opposite the third side of the first triangle is greater than that opposite the third side of the second triangle, then the third side of the first triangle is greater than the third side of the second*).

In this sense of conversion, the passage from a proposition to its converse is not in general a valid inference. And though often a mathematical proposition and its converse may both hold, separate proofs must be given for them. (Ao. C.)

**CONVERTER STEEL.** The principle of removing unwanted constituents from molten pig iron by blowing air through it, converting the iron to steel, was discovered about the middle of the 19th century. Oxygen in the air combined with and literally "burned out" the undesirable elements, as described under *Converter Principles*, below. This article traces the development of the converter process; outlines converter principles, design and operation; and identifies the properties and applications of converter steel. For additional information on the chemical reactions involved and the uses of the process in the steel industry, see IRON AND STEEL INDUSTRY: *Bessemer's Invention*; *Thomas-Gilchrist Discovery*. See also FURNACE, METALLURGICAL: *Converters*; METALLURGY.

William Kelly, of Eddyville, Ky., began experimental work utilizing the principle as early as 1847. During the period when Kelly was developing his process, Henry (later Sir Henry) Bessemer (q.v.) of England independently conceived a similar steel-making method, which he made public in 1856, and the process came to be known as the Bessemer process. With the perfection of converter technique, it became possible to produce low-cost steels (alloys of iron and carbon) of good quality by the ton and at a rapid rate, as compared to earlier methods which produced only small quantities of steel by slow and costly methods. This brought about an industrial revolution, a change from the age of iron to the age of steel. The Bessemer process and others employing similar principles (such as the Peirce-Smith process for converting copper) are sometimes referred to generically as pneumatic processes because of the use of air (or other oxidizing gases) as the means for purifying the metal. Commercial success of the Bessemer process was due to an Englishman, Robert Mushet, who in 1856 recognized the necessity of adding manganese for deoxidation and recarburization following the blow (see MANGANESE STEEL). G. F. Göransson of Sweden, who improved converter

design and operation, also contributed to the early success of the process in 1858 by increasing the tuyère (nozzle for the injection of air) area and decreasing the air volume.

**Converter Principles.**—Molten pig iron, gaseous oxygen and steel scrap are the main constituents for making steel in the converter. Pig iron contains carbon, manganese, phosphorus, sulfur and silicon, in addition to iron. Steel contains similar constituents, but in different proportions. Steelmaking, therefore, consists of eliminating or adding certain constituents which control the properties of the ultimate product. All the elements discussed, including iron, have a strong affinity for oxygen, which in the converter process may be obtained from air, oxygen-enriched air, pure oxygen, steam-oxygen mixtures or additions of iron oxide. Oxygen enrichment of the blast increases thermal efficiency, permitting the melting of additional scrap. The use of steam with oxygen instead of air decreases thermal efficiency but results in a low-nitrogen steel. The reaction of all these elements with oxygen results in the production of heat.

The essential principle of the converter process consists of blowing air through a body of molten metal or introducing oxygen onto the surface of the molten metal, thus rapidly oxidizing the various elements, which enter the slag or, in the case of carbon, leave the converter as a gas. The heat generated is sufficient to maintain the metal in a liquid state and melt some scrap. At the end of the blow the vessel contains metal covered with a layer of slag. In order to convert the molten metal into steel, manganese, silicon, carbon and a small amount of aluminum are added. Proper deoxidation and additions of suitable elements make the steel suitable for rolling and fabrication. Positions in the operation of a bottom-blown converter are shown in fig. 1.

Converter steel is designated as either acid or basic depending on whether the converter lining is composed primarily of silica (acid), and an acid slag is produced; or of dolomite lime or magnesite (basic) and a basic slag is produced. The early converters were acid converters, and in this process, which is the one used in the United States, carbon, silicon and manganese are removed during the blow. Molten iron for the acid process must be low in sulfur and phosphorus, as these elements are not oxidized or removed. After the Bessemer converter process had been successfully developed, open-hearth and electric-furnace processes to produce basic steel were introduced; and by 1910 the production of open-hearth steel in the United States surpassed that of Bessemer converter steel. One of the reasons for this was the almost complete change from the use of acid Bessemer rails to basic open-hearth steel rails, which were of more uniform quality. Later, growth of the automobile industry created a demand for even larger quantities of basic open-hearth steel. In addition, the open-hearth process made possible a greater utilization of scrap and produced steel with a lower nitrogen and phosphorus content.

Beginning in 1878, an Englishman, Sidney Gilchrist Thomas (q.v.), developed a basic bottom-blown converter process utilizing (1) a basic lining; (2) basic flux; and (3) an afterblow. This is the Thomas process, and carbon, manganese, silicon, phosphorus and sulfur are removed during the blow. Phosphorus elimination occurs after removal of carbon during a period known as the afterblow, in which the phosphorus is oxidized and combines with a basic slag containing lime.

In western Europe the Thomas process retained its position as a major process for producing carbon steels. The smelting of high-phosphorus ores in Europe resulted in high-phosphorus pig iron ideally adapted for steelmaking, provided that the basic-lined converter was used. The basic converter steelmaking process which utilizes an oxygen lance or jet (fig. 2) was experimentally introduced in 1949, and several plants were placed in operation in the 1950s.

**Converter Design.**—There are no essential differences between the design of the bottom-blown acid and basic converters as shown in fig. 2, except for the bottom construction. Both types of converters are blown through an arrangement of tuyères which are below the molten metal and above the wind box.

In 1862 Bessemer developed a side-blown converter, but it was not until 1891 that F. A. Tropenas designed a converter with the

BY COURTESY OF U.S. STEEL CORP.

FIG. 1.—SCHEMATIC DRAWING OF THE POSITIONS IN THE OPERATION OF A BOTTOM-BLOWN CONVERTER SHOWING (A) CHARGING; (B) BLOWING; (C) POURING

air blast directed upon the surface of the bath through the side of the converter. This type of converter with an acid lining became known as the Tropenas side-blown converter and is used in the steel foundry. A basic lining may also be used in a side-blown converter.

Bessemer in 1856 recognized the possibility of using pure oxygen in the converter process, but the cost was prohibitive. When oxygen is directed through a lance downward on the bath of a solid-bottom converter the process is called the basic oxygen converter process. This process, also called the basic oxygen steel process or basic oxygen furnace process, is used both in Europe and the United States. Carbon, manganese, phosphorus, sulfur and silicon are removed from the iron. An afterblow is not required for phosphorus removal providing the phosphorus content of the iron is not too high. Appreciable quantities of scrap may be melted.

The rotating basic converter using an oxygen lance which is directed at the surface of the molten metal was developed during 1948 in Sweden. The lance is located in one end of a rotating refractory-lined vessel. Rotation increases the slag-metal reaction. Operation of the converter is similar to the basic oxygen furnace converter.

In a converter steel plant one of the vessels shown in fig. 2 is the principal unit. In the acid process a siliceous material (micaceous schist or sandstone) and in the basic process calcined dolomite or magnesite are used for the lining. The capacity of the vessel varies from 2 tons for an acid side-blown foundry converter to 200 tons for a basic oxygen converter. The normal capacity of a bottom-blown converter is 30 tons. The detachable bottom developed by Bessemer in 1863 consists of tuyères for the introduction of the air blast at 20–30 lb. per square inch (p.s.i.) from the wind box to the liquid metal. In the side-blown converter, tuyères for air at 5 p.s.i. are located on one side of the vessel above the molten iron.

In the top-blown oxygen converter process, pure oxygen at 125 p.s.i. is introduced with a water-cooled lance through the mouth of the vessel. The vessel is supported on trunnions and may be rotated through an angle of 360° by two independent electric motors. A hollow trunnion for the air blast from the turboblowers is used for bottom-blown converters.

**Converter Operation.**—The operation of a top-blown concentric solid-bottom converter is illustrated in fig. 3. The mouth or top of the vessel is concentric in shape, and it may be charged on one side and tapped or discharged on the opposite side. Scrap is charged to control the temperature; and molten pig iron with about 4% carbon from a storage vessel called a mixer, or directly from a blast furnace, is then added to the converter. The bottom-blown converter is charged in a similar manner.

The charged converter is rotated into the blowing position, and air is introduced through the bottom as shown in fig. 1 (an eccentric type of converter charged and tapped from the same side). In the bottom-blown acid converter, a short transparent flame extends from the mouth of the converter during the first period or silicon blow. The flame starts to lengthen after about four minutes, and the second period or carbon blow begins. Manganese

is removed during both periods. If the blow becomes too hot, steam may be added with the air. If the blow becomes too cold, the vessel may be side-blown by turning the vessel to a nearly horizontal position. The bath boils and the flame may extend 30 ft. above the mouth of the converter. As the flame gradually drops, the colour changes from golden yellow to red, and this change is designated as the end point which may be determined by the spectrograph or photoelectric cell. In the acid process, the bath contains about 0.04% carbon at the end point. In the bottom-blown basic process, an afterblow, controlled by timing the blow after a chemical analysis of the bath is obtained, occurs for several minutes after the end point. Also in the basic process, flux materials such as lime and iron oxide are added to remove phosphorus.

The side-blown acid converter is similar in operation to the bottom-blown acid converter. Reactions are started by blowing air through the tuyères located on the side of the vessel and by rocking the converter if necessary. In side-blowing, the temperature of the blow is increased by oxidation of carbon monoxide to carbon dioxide inside the vessel above the bath. Also, since the nitrogen of the air is not blown through the molten metal as in bottom-blowing, side-blown converters can produce steel with a

FIG. 2.—TYPES OF CONVERTERS: (A) BOTTOM-BLOWN ACID CONVERTER; (B) BOTTOM-BLOWN BASIC CONVERTER; (C) SIDE-BLOWN ACID CONVERTER; (D) TOP-BLOWN BASIC OXYGEN CONVERTER

lower nitrogen content than bottom-blown converters.

In the top-blown oxygen converter process shown in fig. 3, a water-cooled oxygen lance is inserted into the converter after it is rotated into the blowing position. A hood for collection of fumes is placed over the converter mouth. Pure oxygen is introduced and impinges on the surface with formation of iron oxide. Carbon reacts with the iron oxide to form carbon monoxide, which provides a vigorous boiling action and accelerates the refining reactions without emission of iron pellets. The blowing time may vary from 10 to 30 min., and one to three blows may be produced per hour. Lime or limestone, mill scale, fluorite and sometimes dolomite are added at the beginning and during the blow to produce a suitable slag. The end of the blow is determined by chemical analysis of the bath. In the basic oxygen converter vessel shown in fig. 2, blown metal may be poured through a tap hole on the side of the vessel, which separates the slag.

The blowing time of an acid or basic bottom-blown converter also may vary from 10 to 30 min. and one to three blows may be produced per hour. At the end of a blow, ferromanganese, ferrosilicon or carbon may be added to the vessel or to the ladle as the metal is poured from the vessel into the ladle. In addition, aluminum may be added to the ladle, particularly if it is desired to render the nitrogen content of the steel inactive. Carbon is added as anthracite coal, graphite or, in the acid process, as molten iron. Steel in the ladle is teemed (poured) into ingot molds where special additions may also be made. After pouring the blow, repairs may be made to the lining if necessary, and a new charge introduced. In the basic process, greater care of the lining is required.

**Properties and Applications.**—The properties of converter steel may be similar to open-hearth or electric-furnace steel. However, in certain types of converter steel, the phosphorus, sulfur or nitrogen may exceed that usually found in open-hearth steel. Larger quantities of these elements will change the properties of the material. Therefore, when the phosphorus or nitrogen exceeds that found in open-hearth steel, converter steel may require special treatment, which may involve either deoxidation practices in making the steel or thermal treatment after rolling.

The acid and basic bottom-blown converter steels are used for the production of butt-welded pipe, seamless pipe, free-machining and reinforcing bars, certain flat-rolled products and several types of wire, and as blown metal for the basic open-hearth duplex process (see IRON AND STEEL INDUSTRY: Variations in Process). Acid side-blown converter steel is used for the production of steel castings. Basic oxygen furnace steel is low in nitrogen and used

principally for low-carbon strip, plates, tubular products, structural shapes, bars and wire products. Converter steels have tensile properties, fatigue properties, corrosion resistance, high strength properties and welding characteristics similar to open-hearth steels having comparable compositions.

### CONVOICATIONS OF CANTERBURY AND YORK.

The word convocation (from Lat. *convocatio*, a "calling together") refers to any assembly of persons who have been called together. The term is applied with a narrower meaning to a number of bodies in universities and elsewhere and, in England, especially to two ecclesiastical assemblies, namely, the convocation of the province of Canterbury and the convocation of the province of York. In Europe the expression has usually been confined to assemblies of bishops; but in England each convocation has consisted, and does consist, of two houses, an upper house of bishops and a lower house of the inferior clergy.

Their origin can be traced back before the Conquest. Later they became, in effect, a parliament wherein, in addition to transacting ecclesiastical business, the clergy taxed themselves for the benefit of the royal exchequer. Indeed, provincial synods for the discussion of purely ecclesiastical business were called by legates or archbishops on their own authority, usually when parliament was not sitting; while the convocations were summoned by the archbishops, usually in response to a royal writ during the time of parliament, in order to provide money for the king and to deal with his business.

At the Reformation, the Act of Submission of the Clergy (1533) provided that convocation was not to meet without the permission of the king. For the next 140 years the convocations were busy with the Reformation settlement, working in close co-operation with the monarch and with parliament. After the Restoration of Charles II in 1660, in compliance with a private understanding between Archbishop Gilbert Sheldon and Lord Clarendon, the lord chancellor, the clergy appear tacitly to have agreed to abandon their claim to tax themselves. In 1663 they voted subsidies for the king; but since then they have been taxed, like the rest of the nation, by parliament and they have exercised the parliamentary franchise. With the Reformation settlement not only apparently accomplished but also firmly consolidated on a statutory basis, and with the business of taxation abandoned, the immediate use of convocation was no longer so apparent.

Convocation, moreover, after the Revolution of 1688, began to exhibit an independence of thought which was embarrassing to the government; particularly over the question of the nonjurors. In 1717 Benjamin Hoadly (q.v.), bishop of Bangor, who had written against the nonjurors, followed this with a sermon preached before George I which also expressed distinctly unusual views about the nature of the church, but which so pleased the king that he ordered it to be published. Upon this the lower house of Canterbury joined issue with the bishop, whereupon the king, to avoid the certain and probably unanimous condemn-

BY COURTESY OF U.S. STEEL CORP.

FIG. 3.—SCHEMATIC ARRANGEMENT OF THE BASIC OXYGEN CONVERTER PROCESS

tion of these views, hastily prorogued convocation. From then until nearly the middle of the 19th century it never met again except to pass some loyal and innocuous motion and then be formally prorogued. Since the mid-19th century, however, it has met frequently, even, in the 20th century, twice or three times a year, and has concerned itself actively with ecclesiastical business, particularly the reform of the canons of ecclesiastical law.

Both convocations have been divided since the 15th century into two houses, the upper consisting of the archbishop and the diocesan bishops of the province, the lower of the deans of the cathedrals and the two senior archdeacons in each diocese (and, in the province of Canterbury, the deans of Westminster and Windsor, and also the provost of Eton, if in priest's orders), all of whom are ex officio members, together with proctors (or representatives) of those clergymen who are beneficed or who hold a bishop's licence to officiate. Proctors must themselves be in priest's orders and in York must be beneficed in the diocese for which they are elected, or resident therein and with a licence to officiate. Clergymen in the universities also return proctors to convocation. Suffragan bishops do not sit in the upper house; but, though not of the inferior clergy, they may sit in the lower house, if by election or otherwise they are qualified; and, since often a suffragan bishop is also an archdeacon, a number of suffragans is to be found in the lower houses of both convocations. Normally the archbishop is the president of the convocation and of the upper house in his province and, in his absence, the senior bishop; but the sovereign would preside, if present, and in the reign of Henry VIII Thomas Cromwell presided as vicegerent and vicar general. The lower house elects one of its number as prolocutor and he presides, when the lower house is sitting alone, and, like the speaker of the house of commons in its dealings with the lords, he represents the lower house in its dealing with the upper house. Joint sittings of both houses together are common, and there have even been joint sittings of both convocations.

Convocation is summoned by the archbishop, who, in obedience to a writ from the sovereign, issues a mandate. In York the mandate issues to each diocesan bishop, requiring him to cite the clergy; in Canterbury it issues to the bishop of London in his capacity as dean of the province. Members of convocation enjoy a similar privilege from arrest as do members of parliament. Convocation is dissolved or prorogued by the archbishop's mandate in obedience to a writ from the sovereign. In 20th-century practice convocation has acted as though it is not dissolved by the demise of the crown, although formerly it was always thought otherwise, and there is no statute governing the matter as there is in the case of parliament. It is generally held, too, that convocation is automatically dissolved by the dissolution of parliament.

The sovereign may issue letters of business to the convocations, when he desires their opinion on any matter. They may also, when lawfully assembled, discuss any other matter of interest to them, and they sometimes pass resolutions known as acts of convocation, which, though influential, have no effect in law. They legislate by passing canons; but their powers in this respect are very limited. They cannot confer to make a canon without the royal licence; every canon requires the royal assent in order to become law; even so, it is invalid, if it be contrary to the royal prerogative, to common law, to statute law or to the general custom of the realm; nor are canons binding except upon the clergy, though, of course, they may thus indirectly affect the laity.

While the legislative powers of convocation are strictly limited, its influence is considerable in reaching and expressing the common mind of the church (or, at least, of a prominent and professional part of it) and in giving a lead in the affairs of the church, though, even here, the effect is lessened by the absence of any lay element. But a misleading picture may be formed, unless account is also taken of the Church of England Assembly (Powers) act, 1919, commonly called the Enabling act, which gave legal recognition and wide powers to the National Assembly of the Church of England, commonly called the Church assembly. This consists of three houses, namely, a house of bishops, a house of clergy and a house of laity. The house of bishops consists of the members of the upper houses of the two convocations; the house of clergy con-

sists of the members of the lower houses of the two convocations; and the house of laity consists of the elected representatives of the laity (together with a few co-opted members). A measure of the Church assembly, on receiving the royal assent, has the full force of an act of parliament. Although, therefore, the legislative powers of the convocations are limited, those of its members are considerable and, further, it must be remembered that 26 of the bishops also have seats in the house of lords. (E. G. Mo.)

**CONVOLVULACEAE**, the morning-glory family of plants, members of which belong to the tube-flowered series of the group of dicotyledons having joined petals. The family contains about

ROCHE  
COMMON MORNING-GLORY (IPOMOEA PURPUREA)

40 genera with more than 1,000 species, and is found in all the warmer parts of the world, but is best developed in tropical Asia and tropical America. The most characteristic members are twining plants with generally smooth heart-shaped leaves and large showy white, pink, blue or purple flowers, as, for instance, the greater bindweed of American and English hedges, *Convolvulus sepium*, and many species of the genus *Ipomoea*, the largest of the family including the common morning-glory of the garden, *I. purpurea*.

The largest genus, *Ipomoea* (true morning-glory), has about 400 species; *Convolvulus* (bindweed) has about 150 species, mainly in temperate climates.

*Cuscuta* (dodder, love vine) has nearly 100 species in the warmer and temperate regions; two are British.

In North America, the largest genera are *Ipomoea*, *Cuscuta* and *Convolvulus*. The creeping or trailing type is common, as in field bindweed (*Convolvulus arvensis*), which has also a tendency to climb, and *C. soldanella*, the sea bindweed, the long creeping stem of which forms a sand binder on temperate seashores; a wide-spread and efficient tropical sand binder is *Ipomoea pes-caprae*. In hot dry districts such as Arabia and northeast tropical Africa occur several genera with a low, much-branched, dense, shrubby habit, with small hairy leaves and very small flowers.

Some exceptional members of the family are represented by *Humbertia* (a native of Madagascar), which forms a large tree; and dodder (*q.v.*), a leafless parasite with slender, yellow, orange or pink threadlike twining stems.

The flowers of the family stand singly in the leaf axils or form cymose inflorescences; they are sometimes crowded into small heads. The bracts are usually scalelike, but sometimes leaflike; e.g., in *Convolvulus spithameus*, *C. hederaceus* and others they are large and envelop the calyx.

The parts of the flower are in fives in calyx, corolla and stamens, with two carpels that unite to form a superior ovary. The sepals, generally free, show much variation in size, shape and covering, and afford characters for the distinction of genera. The corolla is generally funnel-shaped, more rarely bell-shaped or tubular; the outer face is often marked out in longitudinal areas, five well-defined areas tapering from base to apex, and marked with longitudinal striae corresponding to the middle of the petals and alternating with five nonstriated weaker triangular areas. The slender filaments of the stamens vary widely, often in the same flower; the anthers are linear to ovate in shape, attached at the back to the filament and open lengthwise. The ovary is generally two chambered, with two inverted ovules standing side by side at the inner angle of each chamber. The style is simple or branched, and the stigma linear, capitate or globose. The fruit is usually a capsule opening by valves; the seeds, where four are developed, are each shaped like the quadrant of a sphere; the seed coat is smooth, warty or hairy; the embryo is large with generally broad cotyledons surrounded by a horny endosperm.

However, *Cuscuta* has a threadlike spirally twisted embryo with no trace of cotyledons. Some types having large showy flowers are visited by insects for the honey secreted by a ringlike disk below the ovary; large-flowered species of *Ipomoea* with narrow tubes are adapted for the visits of birds.

The tuberlike roots of *Ipomoea batatas* are rich in starch and sugar, and, as the sweet potato (*q.v.*), form one of the most widely distributed foods in the warmer parts of the earth. Several species are used medicinally for the strong purging properties of the milky juice they contain. One of these, jalap (*q.v.*), is derived from *Exgonium purga* (*I. purga*). *Ipomoea* or orizaba jalap, similar in action, is obtained from the dried root of *I. orizabensis*, a native of Mexico. The resinous cathartic scammony is obtained from the root of *C. scammonia*, native to Asia Minor.

Species of *Ipomoea*, *Convolvulus* and *Calonyction* (moon-flower) are cultivated as ornamental plants. *Convolvulus sepium* and *C. arvensis* (bindweed) are pests in fields and gardens and many of the dodders (*Cuscuta*) cause damage to crops.

See MORNING-GLORY; BINDWEED.

**CONVOLVULUS**, a genus of twining plants of the family Convolvulaceae (*q.v.*), commonly known as bindweeds or wild morning-glories, comprising 200 or more species widely distributed in temperate and tropical regions. See BINDWEED; SCAMMONY.

**CONVOY**, a term used in naval warfare to denote one or more merchant or other noncombatant vessels sailing under the protection of warships.

Originally, merchant vessels formed convoys in order to protect themselves against pirates. Since the 17th century neutral powers have claimed the "right of convoy," that is, immunity from search for neutral merchant vessels sailing under the convoy of a warship of the neutral. England, the dominant naval power, refused to recognize this right.

Attempts by Russia in the "armed neutrality" compacts of 1780 and 1800 to secure recognition of neutral convoys were unsuccessful. The United States, Austria and France were among the states which recognized the "right of convoy." Great Britain deviated from its position only during the Crimean War in order to harmonize its practice with that of its French ally. The principal powers, including Great Britain, recognized and formalized the right of neutral convoy in the declaration of London, 1909. The belligerent warship was permitted, however, to ask, in case of suspicion, that ships in the convoy be searched by the commander of the convoy who was bound to give his findings in writing and to withdraw protection from the offending ship in case the suspicion of violation of neutrality was well founded. Any controversy between the neutral and the belligerent commanders was to be settled through diplomatic channels. The London declaration failed to enter into force. During World War I, the right of convoy was invoked on only one or two occasions.

During World War I, convoys were to serve a totally different purpose, namely, the protection of belligerent merchant shipping, largely against German surface raiders and submarines. (See SUBMARINE: *Submarine Warfare*.) There was much controversy in Great Britain about the advantages and disadvantages of convoying vessels transporting vital cargo from the United States and other countries. The German practice of proclaiming as war zones large areas of the high seas and waging unrestricted submarine war on belligerent and neutral commercial shipping left no alternative. In 1917 the convoy system was adopted and justified itself fully during the balance of World War I.

## WORLD WAR II

During World War II, the convoy system was adapted, developed and played a decisive role in achieving victory against heavy odds. To ensure the most rational use of available tonnage, steps were taken to co-ordinate British and U.S. policies. After Pearl Harbor there were two shipping pools (one British and one U.S.) and two centres of control (Washington and London), with an Anglo-American Combined Shipping Adjustment board in general command. British ships were detailed for U.S. service by the British member and U.S. ships were allocated to British service by

the U.S. member. The over-all direction was in the hands of the British prime minister, Winston Churchill, and Pres. Franklin D. Roosevelt, inasmuch as shipping was a function of grand strategy.

Additional measures gradually put into effect to overcome one of the main drawbacks of the convoy system, delay in the assembly and dispatch of convoys, were concerned with avoidance of overcrowding at ports of departure and arrival, and accelerating the turn-round, principally in British and U.S. ports but also in ports in the middle east, Persian gulf, India, Ceylon and elsewhere. It was also found that tonnage could be used to greater advantage by more expert crating of heavy equipment, dehydrating some foods and shipping beef without bones.

In Aug. 1942 the interlocking convoy system was put into effect. This combined into one system coastal convoys in the United States with transatlantic convoys from New York to Britain. The system operated like a railroad on a tight schedule, the coastal convoys being scheduled to arrive just in time for the departure of transatlantic convoys. The coastal convoys operated from Key West and from Guantánamo (Cuba) to New York. The latter were extended in 1943 to Aruba (Netherlands Antilles), Trinidad and finally to Rio de Janeiro with the Brazilian navy participating in the escort from Recife to Rio. Local convoys from the Gulf of Mexico and the Caribbean were fed into Key West and Guantánamo. The effectiveness of the system depended, of course, upon the availability of ships for escort duty both in kind and number.

A convoy consisted of a varying number of merchant vessels, arranged in columns at a predetermined distance from each other, and an escort of warships stationed ahead and on the flanks. The merchant vessels were under the command of a convoy commodore, usually a high-ranking naval officer recalled from retirement for active duty. The entire convoy was under the command of the senior officer in the escort, who in turn was controlled by Washington or London up to "Chop" (change of operational control). The escort commander was authorized to deviate from the prescribed route to meet unforeseen circumstances. He might also order fast (9 knots) or a small convoy to zigzag, or a slow convoy (6½ knots) to steer an evasive course in order to avoid attack. In the latter case, the base course would be changed 20°–40° on each side for a period of several hours.

The escort commander received information regarding enemy submarines and instructions from London or Washington. Information concerning location of submarines was obtained through shore-based or ship-borne high-frequency direction finders (HF/DF, called "Huff-Duff"). Convoys included, after 1942, specially designed rescue ships, and also tankers carrying fuel for escorting destroyers. Escort disposition around convoys was gradually improved to meet changing tactics of submarines. Communication within the convoy was generally by voice radio (TBs) and communication between air escort and surface escort was also provided for. U.S.-Canadian escorts were in charge of convoys from the Atlantic seaboard to "Momp" (mid-ocean meeting point), where they were turned over to a waiting U.K. escort.

Radar as well as sound detection devices like sonar (sound navigation ranging) installed in escorting vessels and microwave radar in aircraft proved most valuable in fighting the submarine and ensuring the safety of convoys, as did refined methods in the use of depth charges and the forward-thrown "squad" adopted by the British navy in 1945. Other types of forward-thrown antisubmarine weapons like the "hedgehog" and "mousetrap" were less effective. The usual weapons carried by escort vessels—guns and machineguns—were also useful against submarines and their crews respectively.

The use of these antisubmarine devices was substantially developed by operations research first instituted in Britain and later adopted by the U.S. navy.

Whereas in World War I the greatest need for protection was for ships in close vicinity of Great Britain, these waters became relatively secure in World War II because of defense by shore-based aircraft. It was on the high seas that there was the greatest need for protection in World War II, although extremely severe losses were inflicted on shipping along the Atlantic coast of the United States during the first few months of 1942, before coastal

convoys were organized. The number of convoys that could be organized in any area depended upon the availability of escort vessels of which initially there were very few on either side of the Atlantic. When the convoy system was introduced in Britain in 1917, 339 destroyers were available for escort duty, and a normal escort consisted of 8 to 10 vessels. In Aug. 1940 Britain disposed of only 181 destroyers and the normal escort consisted of 2 to 3 ships. In the last quarter of 1940, after the consummation of the "destroyer deal" between the U.S. and Britain, the average escort was increased to 8 to 12 vessels but was reduced to 4 to 6 vessels in 1942. Scarcity of escorts also limited the distance over which protection could be afforded. Thus, until spring 1940, convoys were protected for only a short distance and had to make their way across the Atlantic without escort. Between June 1940 and the end of 1941, British shipping consequently suffered a total loss of about 7,000,000 dead-weight tons representing about 36% of the total British merchant fleet in June 1940. The first convoy across the Atlantic under continuous escort sailed over the northern route from Halifax, N.S., on May 27, 1941; over the southern Atlantic route from Sierra Leone on the west coast of Africa on July 14, 1942; and the first convoy on the Gibraltar route on July 10, 1941. In Sept. 1941 the United States began to participate in escorting convoys across the northern Atlantic and the U.S.S. "Reuben James" was sunk by a German U-boat on Oct. 30, 1941. However, in July 1941, the United States had already relieved the British in Iceland and the navy began escorting vessels of any nationality to and from Iceland.

Convoys were primarily concerned with protection of cargo vessels. Troop transports from the United States to Britain, beginning July 10, 1942, also sailed under heavy escort and suffered no loss whatsoever during the entire war with the exception of some losses suffered by troopships to Greenland and Iceland. Fast ships like the French S.S. "Pasteur," Canadian S.S. "Empress of Britain" and the British "Queen Mary" and "Queen Elizabeth" served as troop transports after Aug. 1942, and sailed without escort and without any incident. Even cargo vessels of about 14 knots and over needed no protection and sailed independently.

From 1941 on the German submarine command under Adm. Karl Dönitz replaced attack by individual U-boats by "wolf packs." These consisted of 8 or more, sometimes up to 20 submarines, spread out over probable convoy routes. They were to intercept a convoy and attack it at night. One or two submarines were to lure escorts away from the convoy in order to enable others to close in on, or to penetrate, the convoy. Wolf packs concentrated on transatlantic convoy routes in the mid-Atlantic which, in 1942-43, did not enjoy the protection of shore-based aircraft, and in the Atlantic narrows between Brazil and Africa. As the interceptor submarines reported the sighted convoy to Dönitz, who

directed the rest of the pack to the convoy, it was possible for the Allies to locate the pack. To counter Allied attack from the air, German commanders were instructed to fight back rather than submerge. This proved a costly defense against expanding Allied air superiority.

The Allied answer to the growing menace to convoys was more and better escorts, and arming of the merchant vessels. Gradually, ships were supplied with guns and anti-aircraft guns and armed guards. All available vessels including private yachts were pressed into service. Destroyers and destroyer escorts were most effective for convoy duty but they became available in substantial numbers only by mid-1943. In addition to U.S., Canadian and British, destroyers of such other nations as France, Norway, Poland, the Netherlands and Brazil were included in the screen. In April 1943 escort carriers were added to the screen, thus providing effective air cover outside the range of coastal aircraft. In 1943 the range of these was extended from 600 to 900 mi. from Newfoundland and from 700 to 900 mi. from Britain. The permission granted by Portugal to Britain in Oct. 1943, and to the United States in 1944, to use the Azores as a base made it possible to extend aircraft protection to an area which was known as the "black pit." All these developments permitted the Allies to adopt more aggressive and flexible methods for protecting the convoys by keeping the submarine out of range, and at the same time for destroying the submarine where it was most abundant, namely, in the vicinity of convoys. Escort carriers were instructed to seek out U-boat packs at considerable distances from the convoy. The formation of "hunter-killer" groups, patterned after the British "seek and strike" tactics of following up contact with submarines and destroying them, was the final stage in the evolution of convoy protection and antisubmarine warfare.

Allied shipping losses are detailed on the charts (fig. 1 and 2). Particularly heavy losses occurred after Pearl Harbor in areas under the primary responsibility of the United States. Between January and June 1942, 297 ships (1,612,900 gross tons) were sunk. Allied losses reached the peak in June 1942: 140 ships (700,000 gross tons) sunk in all waters. In March 1943, 95 ships (567,400 gross tons) were sunk in the Atlantic and Arctic. From then Allied losses declined and the destruction of submarines increased. In May 1943, "black May" for German submarines, 41 were sunk. Losses continued heavy in the Indian ocean where no escort and no air protection could be provided. Over the North Atlantic route to Russia, the most dangerous of all convoy routes, which was exposed to the German battle fleet and aircraft based on Norway, 40 convoys carried 4,000,000 gross tons between Aug. 1941 and the end of the war, 720 merchant vessels arriving and 63 vessels being lost. One convoy, the P.Q. 18, consisting of 40 vessels and protected by 77 warships, lost 13 ships. The British home

fleet, which had responsibility for this route, suffered grievous losses keeping Russia supplied. In 1944, the year of D-day, 266 convoys escorted by 2,000 warships sailed over the North Atlantic route to Britain. Of about 13,000 merchant vessels, 10 were sunk. Over the central Atlantic route, between Nov. 1942 and May 1945, 11,000 merchantmen sailed in 189 convoys, 9 ships being lost. The appearance of the "schnorkel" (see SUBMARINE) in 1945 turned the shipping situation against the Allies and for a while brought about losses comparable with those of 1943. This development was too late to make any difference to the Allied cause. Had the schnorkel-type submarine become operational earlier, as Dönitz had planned and hoped, it might have been dan-

OFFICE OF THE CHIEF OF MILITARY HISTORY, DEPARTMENT OF THE ARMY FROM U.S. ARMY IN WORLD WAR II, THE WAR DEPT., "GLOBAL LOGISTICS AND STRATEGY 1940-45," BY RICHARD M. LEIGHTON AND ROBERT W. COAKLEY, 1955  
FIG. 1.—CHART SHOWING THE CONSTRUCTION AND LOSSES OF DRY CARGO SHIPS OF THE U.S. AND ALLIED AND NEUTRAL NATIONS FROM SEPT. 1939 TO JUNE 1943

FIG. 2.—CHART SHOWING THE CONSTRUCTION AND LOSSES OF TANKERS OF THE U.S. AND ALLIED AND NEUTRAL NATIONS FROM SEPT. 1939 TO JUNE 1943

gerous because aircraft were not successful against it. It was necessary to revert to the tried and tested method of depth charges but the schnorkel was much more difficult to locate and destroy than its predecessor.

The last battle against a submarine of the schnorkel type was fought off Narragansett bay, Rhode Island, three days before Germany surrendered unconditionally. Convoys were ordered discontinued on May 28, 1945. The total German effort to cut the lifelines of supply of men and material involved nearly 1,200 U-boats of which about 700 were sunk by the Allies while nearly 100 perished for other reasons, taking about 32,000 officers and men with them to the bottom. The British losses in merchant seamen were below 30,000. Out of a total of 5,887 vessels lost (23,176,485 gross tons), 2,700-odd Allied and neutral merchant vessels totaling nearly 15,000,000 gross tons were sunk by submarines in World War II (1939-45). Of these, less than 30% were torpedoed while sailing in convoy, over 60% were unescorted and the rest were stragglers from convoys. From 1939 to 1942, 4,435 Allied and neutral ships (17,408,849 gross tons) were lost from all causes including U-boats. From 1943, when the convoy system became fully operational, to the end of the war, only 1,452 Allied and neutral ships (5,767,636 tons) were lost.

In the spring of 1943, the back of the German submarine warfare was broken and the initiative passed to the Allies. The convoy system kept England supplied, carried essential supplies to Russia and made possible the tremendous build-up of Allied power for the invasions of Africa, Italy and finally of Europe. Among the many types of escort vessels, the escort carriers constructed in the United States were the best answer to the submarine until the schnorkel made its appearance.

### LEGAL ASPECTS

**Neutral Convoys.**—As noted above, the rules concerning the neutral convoys were neither applied nor tested to any extent in World War I. Many jurists, however, continued to adhere to the declaration of London of 1909, that belligerent warships may not visit and search vessels under neutral convoy. There is no evidence that during World War II neutral powers claimed the right of convoy. In order to escape visit and search (*q.v.*), neutrals were offered by belligerents in both wars the opportunity to obtain a cargo or a ship navicert. Great Britain introduced this system in World War I and again in Nov. 1939. A cargo navicert was a document, in the nature of a pass for approved cargo, issued by the belligerent. A ship navicert declared that the entire cargo of the ship had been approved by the belligerent. Originally, absence of a navicert was no ground for, nor was its possession a guarantee against, seizure. It was a convenience offered by Britain to meet legitimate needs of neutrals. By the Reprisal order in council of July 31, 1940, Britain made absence of a navicert

presumption of enemy destination and a ground for seizure.

**Belligerent Convoys.**—The waging of unrestricted submarine warfare even against neutral ships by Germany in World War I persuaded many neutrals to seek the protection of British or U.S. convoys for their merchant vessels. Regarding the legal position of neutral ships in belligerent convoys, there were two theories. According to Anglo-American opinion such ships were liable to capture. The underlying view was that by joining a belligerent convoy the neutral vessel sought to escape legitimate acts of naval warfare, namely visit, search and eventual seizure, by the opponent.

Germany, however, sank neutral ships in belligerent convoys.

Their view was that by seeking the protection of a belligerent convoy, the neutral merchantman joined a military unit of the belligerent and was liable to sinking at sight. Anglo-American legal opinion assimilated the neutral merchant vessel in belligerent convoy to an enemy merchant vessel; German legal opinion assimilated it to a warship.

This point was explicitly recognized in several international arbitrations arising from World War I, in the French Instructions of 1934 and the Italian Law of Neutrality of 1938. Moreover, it was also generally conceded that sailing under belligerent convoy was equivalent to forcible and illegal resistance to visit and search which exposed the vessel to all the consequences, including sinking. This legal consequence appeared further supported by the fact that merchant vessels, both neutral and belligerent, under escort, were armed in World War I as well as in World War II. This deprived them of the protection afforded by international law to merchant vessels generally. Unarmed merchant vessels may not be sunk by surface warships or submarines unless passengers, crew and ship's papers have first been put into a place of safety.

Admiral Dönitz was accused before the International Military tribunal in Nürnberg of waging unrestricted submarine warfare. The tribunal found Dönitz guilty but imposed no sentence on this ground: "In view of all the facts proved and in particular of an order of the British Admiralty announced on May 8, 1940, according to which all vessels should be sunk at sight in the Skagerrak, and the answers to interrogatories by Admiral Nimitz stating that unrestricted submarine warfare was carried on in the Pacific Ocean by the United States from the first day that that nation entered the war, the sentence is not assessed on the ground of his breaches of international law of submarine warfare." Dönitz was acquitted by the tribunal of the charge of sinking British merchantmen on this ground: "Shortly after the outbreak of war the British Admiralty . . . armed its merchant vessels, in many cases convoyed them with armed escort, gave orders to send position reports upon sighting submarines, thus integrating merchant vessels into the warning network of naval intelligence. On 1 October, 1939, the British Admiralty announced that British merchant ships had been ordered to ram U-boats if possible."

The United States Law of Naval Warfare, promulgated by the chief of naval operations, Sept. 1955, states accordingly in article 503b (3): "Enemy merchant vessels may be attacked and destroyed, either with or without prior warning, in any of the following circumstances: 1. Actively resisting visit and search or capture. . . 3. Sailing under convoy of enemy warships or enemy military aircraft." It also declares that "neutral vessels under convoy of enemy warships acquire enemy character and are always liable to capture" (note 10, pp. 5-9) and that "neutral merchant vessels and aircraft acquire enemy character and are liable to the same treatment as enemy merchant vessels and aircraft when

engaging in the following acts: 1. Operating directly under enemy control, orders, charter, employment, or direction; 2. Resisting an attempt to establish identity, including visit and search." Under the constructive resistance doctrine mentioned above, neutral vessels in belligerent convoys appear to be exposed to sinking at sight. However, the measures which had been adopted by the enemy—proclamation of war zones and all-inclusive contraband lists—had left the neutrals only the choice between stopping altogether a profitable trade or choosing the protection of convoys and accepting the attendant risks.

Leighton and Robert W. Coakley (1955). (L. Gs.)

**CONVULSIONS**, the pathological body condition characterized by abnormal, violent and involuntary spasmodic contractions and relaxations of the voluntary muscles, taking the form of a fit. Convulsions may be a symptom resulting from various diseases; e.g., in uremia, eclampsia, rabies, tetanus, hysteria, epilepsy, strychnine poisoning, cerebral tumour and other diseases. They are usually, but not always, accompanied by loss of consciousness. Popularly, the term is commonly restricted to the infantile variety, occurring in association with causes which upset the child's nervous system. The treatment should be prompt but sedative. Convulsions are symptoms of other conditions which must be recognized and properly treated. In infants and children they may be analogous to a chill in the adult which occurs with the onset of some acute diseases. First-aid treatment includes quiet and prevention of injury from falling, biting the tongue or cheek, and bodily warmth and comfort. Medical advice is essential.

(F. L. A.)

**CONWAY, MONCURE DANIEL** (1832–1907), U.S. liberal clergyman and social reformer, was born of Methodist slaveholding parents in Stafford county, Va., on March 17, 1832, and educated at Dickinson college, Carlisle, Pa. While serving in the Methodist ministry, he became converted to Unitarianism and enrolled in the Harvard divinity school, graduating in 1854. Because of his outspoken expression of abolitionist views he was dismissed from his first Unitarian pastorate in Washington, D.C. In Cincinnati, O., to which he then moved, he was active in abolitionist causes, even settling a colony of fugitive slaves at Yellow Springs, O. In 1860 he edited in Cincinnati a short-lived literary journal named after the earlier New England *Dial*, and in 1862 became co-editor in Boston of the *Commonwealth*, an antislavery paper. During the Civil War he went to England to lecture on behalf of the North, remaining until 1884 as minister of a liberal congregation in London, which he served again from 1892 to 1897. Conway contributed to newspapers and magazines in both England and the U.S., and wrote over 70 books and pamphlets on a great variety of subjects—social, religious, political and literary—becoming increasingly free in his views. His most scholarly works, standard for a half-century, are *Life of Thomas Paine*, 2 vol. (1892) and *Collected Works of Thomas Paine*, 4 vol. (1894–96). His *Autobiography* (1904) is valuable for sketches of important 19th-century figures. Conway died in Paris on Nov. 15, 1907.

See Mary Elizabeth Burtis, *Moncure Conway, 1832–1907* (1952), which contains a bibliography.

**CONWAY, ROBERT SEYMOUR** (1864–1933), English classical scholar, was noted for his service to classical learning through his support of the classics and, in smaller degree, of the study of Indo-European philology, in particular of the ancient languages of Italy. He was born on Sept. 20, 1864, the son of a Congregationalist minister in London. He was educated at the universities of London and Cambridge, winning various distinctions and honours. From 1893 to 1903 he was professor of Latin at University college, Cardiff, and from 1903 to 1929 at the University of Manchester. His most important work was his *Italic Dialects* (1897). A successful teacher, he also won renown for his

research and as a lecturer in the United States, New Zealand and elsewhere. Conway was a man of great enthusiasm for the cause of classical learning, but of fiery temper and at times of unwise judgment. He died in London on Sept. 28, 1933.

See J. Whatmough, "R. S. Conway," *Biographisches Jahrbuch für Altertumskunde*, vol. 266, pp. 21–40 (1939), supp. to K. Bursian, *Jahresbericht über die Fortschritte der klassischen Altertumswissenschaft* (1873 et seq.). (J. Wh.)

**CONWAY** (CONWY; formerly ABERCONWY), a municipal borough of Caernarvonshire, Wales, lies astride the Conway estuary 15 mi. E.N.E. of Bangor and near the easterly entrance of the Menai strait. The borough (charter 1284) also comprises the towns of Deganwy and Llandudno Junction. Pop. (1961) 11,392.

From its rock above the river at the southeastern corner of the town walls, the castle (c. 1284) dominates Conway, one of Europe's few almost perfectly walled towns. The castle is roughly rectangular with four towers, each 40 ft. in diameter, along both sides. The town walls describe a harp-shaped circuit of about 1,400 yd. with 21 towers rising above the general level. Originally there were three main entrances to the town, each with two strong towers. In modern times the walls have been breached at three further points. Castle and walls were constructed by the conquering Edward I as part of his policy of establishing English boroughs along the north Wales coast. In doing so he moved the Cistercian abbey of Aberconwy, burial place of Llewelyn the Great, up river to Maenan. The unfinished abbey church (c. 1185) became the parish church of St. Mary. While at Conway castle in 1399 Richard II was betrayed by the earl of Northumberland to Henry Bolingbroke (afterward Henry IV). During the Civil War the castle was garrisoned for the royalists by John Williams, archbishop of York (a native of Conway), but in 1646, appreciating that the cause was lost, he assisted in delivering the town to Gen. Thomas Mytton to save it from destruction. The castle was partly dismantled in 1665 but, with the town walls, is now in the care of the ministry of works.

The original street pattern seems to have changed little. A 16th-century drawing shows High street, Castle street and Upper Gate street on their existing sites. Aberconwy, a medieval house (c. 1500) at the junction of High street and Castle street, now belongs to the National trust. Plas Mawr ("the great house"), an Elizabethan mansion (1577–80), houses the Royal Cambrian Academy of Art. The Black Lion, Castle street, built in 1582 as a vicarage, was later used as a coaching inn.

From the eastern end of the castle the river is spanned by Thomas Telford's graceful suspension bridge (1826), Robert Stephenson's tubular railway bridge (1848) and the modern road bridge opened in 1958. Conway is on the Chester-Bangor trunk road and the Euston-Holyhead main line, with branch line services.

Since Roman times mussels have been gathered in the estuary—originally for their pearls. A small coastal fishing fleet is based on the town which is a holiday and tourist centre. There is some boatbuilding; agriculture predominates in the surrounding area.

**Deganwy.**—In 517, Maelgwyn Gwynedd, who is said to have succeeded King Arthur as king of Britain, built his castle there. A later Norman castle was captured and completely demolished by Llewelyn ap Gruffydd (c. 1262). The town (Gannow) had been granted a charter by Henry III (c. 1252) and was gradually fused, after 1284, into the new borough of Conway. Little remains of the old fortifications. The Deganwy Castle hotel (c. 1640) is one of the oldest buildings. Deganwy is now a holiday resort, residential area and yachting centre.

**Llandudno Junction** is within the ancient parish of Llangwstenin where, formerly, there were a few scattered farms and residences. With the coming of the railway a community sprang up taking its name from the junction station, one of the busiest in north Wales. This is now the industrial portion of the borough containing a large domestic appliance factory and several storage and distribution depots. (R. C. Gr.)

**CONWAY OF ALLINGTON (WILLIAM) MARTIN CONWAY**, 1ST BARON, of Allington, Kent (1856–1937), Eng-

lish art historian and mountaineer, was born at Rochester, Kent, April 12, 1856, and was educated at Repton school, Derbyshire, and at Trinity college, Cambridge. After a period of European travel and university extension lecturing (1882-85), Conway held the Roscoe chair of art at University college, Liverpool (1885-88). He was Slade professor of fine arts at Cambridge, 1901-04, and director-general of the Imperial War museum, London, from 1917. His most enduring contributions to the history of art are *The Van Eycks and Their Followers* (1921; as *Early Flemish Artists*, 1887), and *The Literary Remains of Albrecht Dürer* (1889). He formed a great library of about 100,000 photographs and reproductions of works of art which he gave to the University of London Courtauld Institute of Art in 1932.

It was for his achievement in surveying 2,000 sq.mi. of the Karakoram in 1892 that Conway was knighted (1895). During this survey he made the first ascent of a major Himalayan peak, reaching 23,000 ft. He produced several books on mountain climbing including *The Zermatt Pocket Book*, the prototype of the handbook for climbers not using guides. *The First Crossing of Spitsbergen* (1897) was a record of his pioneer journey across the main island (1896-97). During expeditions to South America in 1898 he climbed Aconcagua (22,834 ft.), Sorata (Illampu) (21,276 ft.) and Illimani (21,184 ft.); and explored Tierra del Fuego.

Conway was Unionist member of parliament for the combined English universities' constituency from 1918 until his elevation to the peerage in 1931 (at the instance of Ramsay MacDonald). He considered his best book to be *The Crowd in Peace and War* (1915). He died in London on April 19, 1937.

See Lord Conway, *Episodes in a Varied Life* (1932), *A Pilgrim's Quest for the Divine* (1936).

**CONWELL, RUSSELL HERMAN** (1843-1925), U.S. clergyman and the most noted lecturer of the Chautauqua circuit, who for years toured the country with his famous lecture "Acres of Diamonds," was born in South Worthington, Mass., on Feb. 15, 1843. He entered Yale university in 1860. In 1862 he raised a company to serve in the American Civil War, and attained the rank of lieutenant colonel. In 1865 he was admitted to the bar. He practised law in Minneapolis and Boston, and later published two newspapers—the *Minneapolis Daily Chronicle* and the *Somerville (Mass.) Journal*. A run-down Baptist church in Lexington, Mass., enlisted his interest, and when he succeeded in reviving it, he was ordained its minister in 1879. In 1882 he was called to Grace Baptist Church in Philadelphia, a small congregation struggling with debt. Within ten years the church had a new home—the Baptist Temple—and was well on its way to becoming the largest and most famous "institutional" church in the country, with a university and three hospitals numbered among its progeny. The university was Temple, which Conwell started in 1884 as a series of night study courses for ministerial students, received a college charter in 1888 and became a university in 1907, with Conwell as its first president.

Conwell delivered his lecture "Acres of Diamonds" no fewer than 6,000 times with total earnings, including royalties from its sale in printed form, of \$8,000,000. The theme of the lecture was that opportunity lurks in everyone's backyard, that everyone can and ought to get rich and then use his money for the good of his fellow men. "Keep clean, fight hard, pick your openings judiciously, and have your eyes forever fixed on the heights toward which you are headed," was his simple formula for success and the central emphasis of his preaching. He died on Dec. 6, 1925.

The authorized biography by Agnes Rush Burr, *Russell H. Conwell* (1926), includes one of the many recensions of "Acres of Diamonds." (W. S. H.)

**CONY** (CONEY), a name originally applied to the rabbit (*q.v.*) and still sometimes used for it, notably in the fur trade. The cony of the old world and of the Bible is a different animal, which is better termed the hyrax (see *HYRACOIDEA*). The true cony, or pika, is a relative of the rabbit. It is a small, stocky guinea-piglike inhabitant of rocky niches in the hills and mountains throughout Eurasia and North America. See *PIKA*.

**CONYNGHAM, GUSTAVUS** (c. 1747-1819), U.S. naval officer, was born in County Donegal, Ire., about 1747. He was

taken to America in his youth and apprenticed to a captain in the West Indian trade. Advancing to shipmaster, he was employed to bring gunpowder from Holland at the outbreak of the American Revolution, but became stranded in Holland. The American commissioners in France supplied him with a commission dated March 1, 1777, and sent him forth from Dunkerque in May in an armed lugger. He captured a packet plying with mail between England and Holland and brought it and another prize back to Dunkerque. Upon British protest, Conyngham and his crew were imprisoned, the prizes restored and the captain's commission confiscated. The commissioners secured his release, supplied him with a new commission and the cutter "Revenge," and sent him again on a cruise out of Dunkerque. Sailing around the British Isles and operating off Spain and in the West Indies, he took 29 prizes in the ensuing two years, but was finally captured, carried to England, and threatened with death as a pirate. Amid threatened reprisals on the part of the continental congress, Conyngham escaped to Holland, where, in 1780, he joined John Paul Jones in a cruise in the frigate "Alliance." From the end of the war until his death in Philadelphia on Nov. 27, 1819, he waged a hopeless fight to gain recognition by congress of his rank in the navy. Almost a century after his death the commission the French had confiscated and which could have substantiated his claim was found in the collection of a Parisian autograph dealer. (W. B. C.)

**COOCH-BEHAR**, a town and district in northern West Bengal, India, to the south of the Himalayas. The town (pop. [1961] 41,922) is situated on the east bank of the Torsa river, 275 mi. N.E. of Calcutta, and is connected with that city by air and rail. It is planned with a grid pattern of streets, beautifully laid out parks and deep tanks, or artificial lakes. Lansdowne hall, with a clock tower 79 ft. high, constructed in 1892, stands on the west of the Sagardighi, the largest and finest of the tanks.

COOCH-BEHAR DISTRICT forms part of the piedmont plains of north Bengal, sloping gently southward from 180 to 150 ft. Pop. (1961) 1,019,806; area 1,289 sq.mi. The Jaldhaka, Torsa and Raidak are the important rivers; the Tista just touches the district on the west. The shifting of river courses is very common. Just below high riverbanks, loamy and well-drained soils yield rich crops of rice and jute. Tobacco and sugar cane are usually grown on higher ground. The district is a land of foliage and flowers and in its forests roam rhinoceros, tiger, and gaur or "Indian bison."

Dinhata (pop. [1961] 11,306), a market town, stands on Rangpur road, 16 mi. S. of Cooch-Behar town. Matabhanga (pop. 6,980), the largest tobacco-marketing centre, is on the right bank of the Jaldhaka river. Haldibari, Mekliganj and Tufanganj are the other market towns. Cooch-Behar was a princely state before its merger with West Bengal (1950). (S. P. C.)

**COOK, ARTHUR JAMES** (1883-1931), British labour leader, who became widely known during the 1920s for his championship of the miners' cause, was born on Nov. 22, 1883, at Wookey in Somerset, the son of a professional soldier. Cook started work as a farmer's boy but he migrated to the Rhondda valley in south Wales at the age of 16 and became a coal miner. He studied at the Central Labour college, London, in 1911-12. During World War I he was a strong pacifist and in the aftermath a prominent local agitator. In 1918 and again in 1921, his trade-union activities led to prison sentences. In 1924 he was elected secretary of the Miners' Federation of Great Britain and in the following years of bitter industrial strife he symbolized the determined but ineffective resistance of the miners. He was an impassioned orator with a great following in the coal fields. As a negotiator he was much less successful, and his part in the general strike of 1926 received considerable criticism from other trade-union leaders. He died in London on Nov. 2, 1931. (R. J.)

**COOK, JAMES** (1728-1779), English circumnavigator, hydrographer, and explorer of the Pacific and Antarctic oceans, who in three great voyages from 1768 to his death did more to clarify the geographical problems of the southern hemisphere than had been done by all his predecessors. He was the first of the really scientific navigators and his voyages made great contributions to many fields of knowledge besides geography. His charting of the

North American coast on its Pacific side alone is a work of considerable importance.

Cook was born on Oct. 27, 1728, in the village of Marton-in-Cleveland, Yorkshire. His father, a day labourer, shortly became hind, or foreman, on the farm of Thomas Scottowe at Great Ayton, where Cook spent his boyhood, attending the village school at Scottowe's expense. At the age of 17 he was apprenticed to a grocer and haberdasher of Staithes; but finding himself more strongly attracted to the sea, his apprenticeship was transferred in July 1746 to John Walker, a well-known Quaker shipowner and coal shipper at Whitby, with whom his friendship was lifelong. Cook's ability struck Walker, who sent him to sea at once, while keeping him home in the winter working hard at mathematics and navigation. Out of indentures, he spent two years before the mast in the Baltic trade, returned to Walker's service (1752) as a mate, and in 1755 was offered a command. The experience he had gained of the navigation of colliers on the treacherous east coast of England was an invaluable foundation for his later work.

Instead of accepting Walker's offer of a ship he took the chance of a wider life offered by the near outbreak of war with France, and on June 17, 1755, volunteered into the navy as an able seaman. His first ship was the "Eagle" (60 guns); within a month he was promoted to master's mate and, after channel service (1755-57), to master in the "Pembroke" (64 guns). In Feb. 1758 the "Pembroke" crossed the Atlantic to take part in operations under Adm. Charles Saunders—the siege of Louisburg and the naval side of the assault on Quebec. In the charting of the St. Lawrence before the fleet moved up Cook played an important part; after the capitulation of Quebec he was transferred to the "Northumberland," the flagship of Lord Colville, who succeeded Saunders. While her master he improved his mathematical and astronomical knowledge, learned surveying from Samuel Holland, the military engineer, and built up a high reputation as a marine surveyor. In 1763, after a brief period in England, he was appointed to the Newfoundland survey, commanding the schooner "Grenville," making detailed observations in the summer and returning to England in the winter for desk work on his charts. These were published, at first by Cook himself, later in the *North American Pilot*. During this period, in 1766, he observed very accurately an eclipse of the sun from Burgeo Islands; the observations, and a calculation of the longitude therefrom, were published in the Royal society's *Philosophical Transactions* for 1767, with the remark that the observer was "a good mathematician and very expert in his business." It was therefore as a good seaman, a good hydrographer and a good observer that Cook could be commissioned by the admiralty in 1768 as lieutenant in command of H.M.S. "Endeavour Bark," a Whitby-built collier bought into the navy to take out observers to Tahiti (discovered by Capt. Samuel Wallis) to observe the transit of Venus for the Royal society. The two observers appointed by the society were Charles Green and Cook himself.

The "Endeavour" had two missions. The first was to ensure that the transit was observed as the British part in an international scientific effort which had for its object the determination of the earth's distance from the sun. The second was to carry on the process of geographical discovery set in motion by the admiralty with Adm. John Byron's voyage of 1764-66. Cook's instructions were, after leaving Tahiti, to sail south to latitude 40° S. in search of supposed continental land, and if he did not meet with it to turn west and pick up the coast of New Zealand, last visited by Abel Tasman in 1642-43; then to return home via Cape Horn or the Cape of Good Hope, as seemed to him best. The ship sailed from Plymouth on Aug. 25, 1768. On board also were the young Joseph Banks and his friend the Swedish botanist Daniel Solander, excited by the prospect of natural history studies in the Pacific. Cook entered the Pacific around the Horn and passing through the Tuamotu Islands anchored at Tahiti on April 13, 1769; on Point Venus the necessary observations, seemingly good ones, were carried out on June 3; but unfortunately the nature of the planet made all observations, wherever taken, uncertain, and the subsequent calculations varied so violently as to destroy the value of that side of the voyage. Cook had, however, maintained excellent relations with the Tahitians, of great value for the future, while the

ethnological and botanical work of Banks and Solander laid the foundation for similar work subsequently done in the area. Leaving Tahiti on July 13, Cook first visited and named the Society Islands and then struck south. Unsuccessful in finding a continent, he sighted New Zealand near Poverty bay on Oct. 7, and proceeded to circumnavigate the islands in a figure of eight, making friends with the New Zealanders after some preliminary difficulties, and making also a quite brilliant running survey and chart of the country. On April 1, 1770, he left New Zealand, choosing to return home via the hitherto unknown eastern coast of Australia, which he charted equally brilliantly, in spite of deadly peril from the Great Barrier reef on two separate occasions. He then rediscovered Torres strait and passed through it to Batavia, where his ship's company, so far remarkably healthy, fell victims to malaria and dysentery. In spite of a tragic mortality, Cook brought his ship home safely on July 12, 1771, and was promoted commander.

His interest in the continental problem having been thoroughly roused, he now suggested a further voyage which would take advantage of the westerly winds in high latitudes and circumnavigate the globe as far south as possible, the winters being spent refreshing at bases in New Zealand and Tahiti. He was given command of two ships, "Resolution" and "Adventure" (Capt. Tobias Furneaux); left England July 13, 1772; and sailed southeast from the Cape at the end of November. In three antarctic cruises (Atlantic-Indian ocean sector, Dec. 1772-March 1773; Pacific sector, Nov. 1773-Feb. 1774; and Atlantic sector, Jan.-Feb. 1775) he completely dissipated the old continental theory, but was convinced that there must be land somewhere beyond the ice fields. His farthest south was latitude 71° 10' S., longitude 106° 54' W., on Jan. 30, 1774. In between these cruises he made further visits to New Zealand (off which the ships parted, Oct. 30, 1773) and an astonishing series of discoveries and rediscoveries, mainly on a great tropical sweep, Feb.-Oct. 1774, which took in Easter Island, the Marquesas, the Society Islands, Niue, Tonga, the New Hebrides, New Caledonia and a number of smaller islands. On the last part of the voyage he discovered and charted South Georgia and the South Sandwich Islands, and was home again on July 30, 1775. This voyage was notable not merely for a masterly technique in antarctic navigation, in preserving the health of seamen and in hydrographic work but also for its proof of the value of the chronometer as an aid to finding longitude. Cook was elected a fellow of the Royal society and given its Copley medal for his paper on the methods he used in combating scurvy.

Promoted post captain and appointed to a berth in Greenwich hospital, Cook almost immediately volunteered to take command of a third voyage, its object being to examine narrowly the northern Pacific coast of America for a possible northwest passage. He sailed again in the "Resolution" on July 12, 1776, the "Discovery" (Capt. Charles Clerke), his consort, catching him up at the Cape. After leaving the Cape, he called at Van Diemen's Land, New Zealand, Tonga and the Society Islands, before sailing north on Dec. 8, 1777, and discovering the Hawaiian group on Jan. 18, 1778. Thence he made the American coast, working up it as closely as gales would permit, around the Aleutian Islands, through Bering strait and as far north as latitude 70° 44' N. before he was stopped by pack ice. He determined to winter at Hawaii, where, after some coastal surveying, he anchored in Kealakekua bay from Jan. 17 to Feb. 4, 1779. After leaving he had to put back to repair a sprung topmast, and on Feb. 14 was killed in an unhappy scuffle with the natives ashore. Clerke took command and was beaten back again by the ice beyond Bering strait; he too died, of consumption, and the ships returned to England on Oct. 4, 1780, under John Gore.

Cook's career cut him off largely from domestic life; in 1762 he married Elizabeth Batts, who survived him for 50 years. Of six children three died in infancy, and the three sons who lived longer (of whom two entered the navy) were all dead by 1794.

No man was ever better fitted by character, training and native abilities to be a great nautical explorer, and his second voyage was possibly the greatest voyage ever made. He was a supremely good planner and administrator, and his management of seamen

was masterly. No one was ever more greatly admired by men of his own calling.

Cook's *Account of a Voyage Round the World in the Years 1768-71* was published in J. Hawkesworth's *Voyages*, vol. ii and iii (1773); his *A Voyage Towards the South Pole and Round the World* was edited by J. Douglas in two volumes (1784). Cook and J. King's *A Voyage to the Pacific Ocean . . . for Making Discoveries in the Northern Hemisphere* was also edited by Douglas in three volumes (1784). Later editions are *Captain Cook's Journal*, edited by W. J. L. Wharton (1893), and *The Journals of Captain James Cook*, edited by J. C. Beaglehole in four volumes for the Hakluyt society (1955 *et seq.*).

**COOK, SIR JOSEPH** (1860-1947), Australian statesman, who was prime minister in 1913-14, was born in England at Silverdale, Staffordshire, on Dec. 7, 1860. From the age of nine he worked in a coal mine, until he emigrated to Australia in 1885. He entered the New South Wales parliament in 1891, as a member of the new Labor party, but he soon crossed the floor of the house and held office from 1894 to 1899 as a conservative. He was elected member for Parramatta in the first commonwealth parliament (1901), succeeded to the leadership of the Free Trade party in 1908 and became minister for defense under Alfred Deakin in 1909-10. On the defeat of the Labor party in 1913 he became prime minister, but his party was defeated in the 1914 election. In 1917 he joined W. M. Hughes's coalition government, and was for a time a member of the imperial war cabinet in London. Cook was high commissioner in London from 1921 to 1927, when he retired. He died in Sydney on July 30, 1947. An efficient administrator, he was never a commanding figure, and his accession to leadership marked a decline in political enthusiasm after the early drive of the postfederation era. (O. M. R.)

**COOK, THOMAS** (1808-1892), English travel agent who founded Thomas Cook and Son, was born at Melbourne, Derbyshire, on Nov. 22, 1808. Leaving school at the age of ten, he earned his living at various jobs; in 1828 he became a Bible reader and missionary for the Baptist association and later took up the cause of temperance as well. In 1841 Cook persuaded the Midland Counties Railway company to run a special train between Leicester and Loughborough for a temperance meeting on July 5, believed to be the first publicly advertised excursion train in England. In 1844 he entered into a permanent arrangement with the Midland Railway company to place trains at his disposal, for which he would provide passengers. During the Paris exhibition of 1855 Cook conducted excursions from Leicester to Calais, followed in 1856 by the first grand circular tour of Europe. In the early 1860s he ceased to conduct personal tours and became an agent for the sale of English and foreign tickets, the holder of which traveled independently. During the 1880s his firm performed military transport and postal services for England and Egypt. The firm now has agencies all over the world. Cook died July 19, 1892, in Leicester. (W. H. D.)

**COOKE, HENRY** (c. 1616-1672), English bass singer, choirmaster and composer, noted for building up the choir of the Chapel Royal after the Restoration, was born probably at Lichfield, c. 1616, and brought up as a chorister in the Chapel Royal. He fought for Charles I in the Civil War, whence his title of "Captain" Cooke. During the Commonwealth he taught music, and may have studied in Italy. Appointed a bass in the Chapel Royal and Master of the Children at the Restoration, within three years he built up a great choir, although he began with only five former members, and with the order of service forgotten by most organists. His military discipline, combined with an ability to choose the right boys (William Turner, John Blow, Pelham Humfrey and Thomas Tudway were among his earliest Children), and to teach them well, made his work famous. The boys learned not only sight-singing and composition but also how to play the violin, organ, lute and harpsichord.

Probably on Charles II's suggestion, Cooke introduced instrumental music into the services; he also used sackbuts (trombones) in processions to enable the singers to keep pitch. He frequently sang solos at the services, and both Pepys and Evelyn recorded their praise of him. As a composer he contributed to Sir William Davenant's *Siege of Rhodes* (1656) but was mainly concerned with anthems, music for court functions, including coronation music, and the compositions required for his official position. He died at Hampton Court, July 13, 1672. (B. P.)

**COOKE, JAY** (1821-1905), U.S. financier who rendered important services to the federal government during the American Civil War, was born at Sandusky, O., on Aug. 10, 1821. At the age of 18 he entered the Philadelphia house of E. W. Clark and Co., private bankers. Three years later he became a member of the firm. In 1858 he retired from the firm to reorganize some of the abandoned Pennsylvania railways and canals. In 1861 he opened in Philadelphia the private banking house of Jay Cooke and Co. and floated a war loan of \$3,000,000 for the state of Pennsylvania. Cooke was engaged by the treasury department in 1862 as special agent for the sale of \$500,000,000 worth of bonds. He appointed 2,500 subagents and before the machinery he set in motion could be stopped he had sold \$11,000,000 more than had been authorized, an excess which congress immediately sanctioned. To promote the establishment of national banks Cooke organized two, in Washington, D.C., and Philadelphia, soon after such institutions were authorized by congress in 1863. In 1865, when the needs of the government were pressing and the sale of notes by national banks had been disappointing, Cooke's services were again secured. Between February and July 1865 he disposed of three series of notes totaling \$830,000,000. After the Civil War Cooke became interested in the development of the northwest. In 1870 his firm undertook to finance the construction of the Northern Pacific railway, but failed at the approach of the financial crisis of 1873. By 1880 he had discharged all his obligations and had again become wealthy. He died at Ogontz, Pa., on Feb. 18, 1905.

See E. P. Oberholtzer, *Jay Cooke, Financier of the Civil War* (1907). (W. H. D.)

**COOKE, ROSE** (née TERRY) (1827-1892), U.S. writer, whose fiction dealt mainly with New England country life, was born at West Hartford, Conn., Feb. 17, 1827. She was educated at the Hartford Female seminary and then found employment as a teacher. Her intense nature soon found vent in writing, however, and before she was 20 she had contributed to many magazines. She published in 1860 a volume of *Poems*. After her marriage in 1873 to Rollin H. Cooke she was best known for her fresh and realistic stories, though in 1888 she published more verse in her *Complete Poems*. Her chief volumes of fiction were *Happy Dodd* (1878), *Somebody's Neighbors* (1881), *Root-Bound and Other Sketches* (1885), *The Sphinx's Children and Other People's* (1886), *Steadfast*, a novel (1889). She died at Pittsfield, Mass., July 18, 1892.

See Jean Downey, "Rose Terry Cooke: A Bibliography," *Bulletin of Bibliography*, vol. xxi, pp. 159-163 (1955).

**COOKE, THOMAS** (1703?-1756), English author best known for his translation of Hesiod into rhymed couplets, which gave him the nickname of "Hesiod" Cooke, was born at Braintree, Essex, probably on Dec. 16, 1703. His first important work was *The Battle of the Poets* (1725), a poem attacking some of the leading authors of the day, most notably Alexander Pope and Jonathan Swift. Pope later retaliated by mentioning Cooke unfavourably in his *Dunciad*. Cooke wrote many other original works and also translated some Latin works. From 1741 he edited *The Craftsman*. He died in London in Dec. 1756.

**COOKE, SIR WILLIAM FOTHERGILL** (1806-1879), English inventor who worked with Charles Wheatstone in developing the electric telegraph, was born at Ealing, Middlesex, May 4, 1806. In 1836, after attending a demonstration in Heidelberg, Ger., of an experiment in transmitting messages by wire, he began to experiment with electric telegraphy and soon afterward formed a partnership with Wheatstone, who had also been working with the telegraph. In June 1837 they were granted their first patent, but their early model proved too expensive to be practical. The partners quarreled over which should have principal credit

for their invention. The dispute was settled amicably in 1841 but flared again a few years later. While Wheatstone is considered the more important of the two in the history of the telegraph, Cooke at least contributed his superior business skill to the partnership. The patent for the partnership's most important invention, an electric telegraph employing only a single needle, was issued in 1845. Cooke died in Surrey on June 25, 1879.

**COOKING:** see FOOD PREPARATION; HOME EQUIPMENT.

**COOKING UTENSILS:** see HOME EQUIPMENT.

**COOK ISLANDS**, a group of islands in the southwest Pacific, politically a dependency of New Zealand. They have a total land area of 99 sq.mi. and are widely scattered over an area extending from latitude 8° S. to almost 23° S., and between longitude 156° W. and 167° W. Physically they form two contrasting groups. The southern group, or Lower Cooks, consists of volcanic islands (Rarotonga, Aitutaki, Atiu and Mangaia), of low coral islands (Mauke, Mitiaro and Takutea), and Manuae, an atoll. Most have a broken or hilly interior and a fringing coral reef. Rarotonga rises centrally to 2,140 ft.

The seven islands of the Northern Cooks are low coral atolls. Their population (1961) of 2,867 was mainly concentrated on Penrhyn, the largest island (3.8 sq.mi.), Manihiki and Pukapuka. Palmerston, Nassau and Rakahanga supported much smaller numbers and Suvarrow (Suvorov) was uninhabited. These islands produce some copra and most of the Cook Islands exports of pearl shell.

Of the navigators, explorers and missionaries who visited the group from the 16th century onward, the most important were Capt. James Cook in 1773, Lieut. William Bligh in 1789 and the Rev. John Williams in 1823. Led by Williams, the London Missionary society gained a strong footing and was for long the predominant governing and law-making institution. The islands were first proclaimed a British protectorate in 1888 and were annexed to New Zealand in 1901. The total population (1961) of the group was 18,378, of whom about 300 were Europeans. The Cook Islanders are Polynesians closely related in tradition, language and customs to the New Zealand Maoris. After 1945 a large and increasing number of Cook Islanders migrated to New Zealand.

The seat of administration is at Avarua on Rarotonga (1961 pop. 8,676; area 26 sq.mi.), the largest and most important island. Government is by an elected legislative assembly whose decisions must be ratified by a resident commissioner appointed by New Zealand.

The main exports are citrus fruits, tomatoes, copra, manufactured clothing and jewelry, and pearl shell. Trade is mostly with New Zealand. Despite the predominantly agricultural economy nearly one-third of imports consist of foodstuffs. Until 1960 a fortnightly flying-boat service connected Aitutaki with Tahiti and Fiji; a monthly steamer service links Rarotonga with New Zealand. Transport within the group is by schooners or small craft.

See Department of Island Territories, *Reports on the Cook, Niue and Tokelau Islands* (annually).

(R. M. Fr.)

**COOKSTOWN**, a market town and urban district of County Tyrone, N.Ire., 45 mi. N.W. of Belfast. Pop. (1961) 4,969. It is bounded on the north and west by the Sperrin mountains, and on the south and east by the Ballinderry river, which has free trout and salmon fishing. This plantation town, named after Alan Cook who founded it in the 17th century, consists of one long, wide street with several branch streets. Its main industries are millinery including fur felt hats, and corsetry. Cookstown, which is rapidly expanding, lies 6 mi. S.W. of Lough Neagh and is served by bus transport. About three miles south rises the Rath of Tullaghoge, former residence of the O'Hagans, justiciars of Tyrone; the O'Neill chiefs of Ulster were inaugurated there until the inauguration stone was destroyed by Lord Mountjoy in 1602.

(A. Mv.)

**COOKTOWN**, a seaport of Queensland, Austr. It lies at the mouth of the Endeavour river at the foot of Cape York peninsula, 1,359 mi. N.N.W. of Brisbane by road. In 1770 Capt. James Cook beached the "Endeavour" there to repair damage. Cooktown became a municipality in 1876, having been founded

in 1873 to serve the Palmer gold field (now inactive) to the westward, with which it was linked by rail in 1885. Pop. (1954) 447.

It is a port of call on the steamer route between Brisbane and Thursday Island and is a centre of the *bêche-de-mer* and pearl fishery on the Great Barrier reef. Tin is mined in the area. Cooktown is the chief port of Queensland for the New Guinea trade, and became the seat of a Roman Catholic vicariate in 1887. Airline services link it with Cairns and Thursday Island.

**COOKWORTHY, WILLIAM** (1705–1780), English potter renowned for his discovery in Cornwall of the only supply of china clay (kaolin) and china stone (petuntse) in England, and the first man to produce in England a hard-paste (or true) porcelain, similar to the Chinese and the German, was born at Kingsbridge, Devon, on April 12, 1705. At 14 years of age he began his apprenticeship with a London apothecary named Bevans, who afterward set him up in business in Plymouth under the title of Bevans and Cookworthy. In England the manufacture of porcelain was first attempted about 1745, when factories producing soft-paste (or artificial) porcelain were established. In 1745 Cookworthy entertained André Duché, who, having discovered in Virginia a supply of china clay and china stone, from which he had made true porcelain, wished to set up an export trade to England. A few years later Cookworthy located "immense quantities" of both these materials near St. Austell, Cornwall. He made many experiments before taking out a patent in 1768 and establishing the Plymouth China factory for the production of hard-paste porcelain. He died at Plymouth on Oct. 17, 1780.

See F. S. Mackenna, *Cookworthy's Plymouth and Bristol Porcelain* (1946).

(H. Tr.)

**COOLEY, CHARLES HORTON** (1864–1929), was one of the pioneers in the development of sociology in the United States. He was born in Ann Arbor, Mich., on Aug. 17, 1864. He graduated from the University of Michigan, and beginning in 1892 taught there for 37 years, from 1894 in the then new field of sociology. His contributions appear in three published works. *Human Nature and the Social Order* (1902) presents a socio-psychological approach to the understanding of human society. It is mainly concerned with the social determination of the self, arising through interaction with other persons. From this follows Cooley's fundamental theory that the mind is social and society mental. In *Social Organization* (1909) he presents what may be regarded as the objective consequences of his psychological views. There it is shown that the ideal of moral unity, involving qualities of loyalty, justice and freedom, is derived from participation in primary groups where face-to-face relationships are sustained, as in the family and in play or neighbourhood groups. In the absence of such moral experience, social disorganization is likely to develop. Consistent with these socio-psychological views is Cooley's treatment of institutions which he regards as established phases of the public mind. In a final work on *Social Process* (1918) Cooley made a sociological application of the Darwinian principles of natural selection and adaptation.

If the foregoing views appear somewhat philosophical, it is to be noted that Cooley regarded social reality as qualitatively different from physical reality, and therefore less subject to measurement. Cooley died at Ann Arbor on May 8, 1929. See also *SOCIOLOGY*.

(A. E. Wd.)

**COOLEY, THOMAS MCINTYRE** (1824–1898), U.S. educator and jurist, well known for his writings on U.S. constitutional law, was born near Attica, N.Y., on Jan. 6, 1824. Moving to Michigan in 1843, Cooley was admitted to the Michigan bar in 1846. In 1857 the Michigan legislature chose him to compile the state statutes, and from 1858 to 1865 he was official reporter to the state supreme court. In 1859 the regents of the University of Michigan appointed Cooley one of three professors in the newly organized law department. For years he was secretary, and later the first dean of the department, concurrently serving as a state supreme court justice from 1864 to 1885. In 1884 Cooley resigned his law professorship. Failing re-election to the state supreme court, he accepted a history professorship at the University of

Michigan. From 1887 to 1891 he served as chairman of the newly established U.S. Interstate Commerce commission, doing much to shape its policies. Between 1889 and his death at Ann Arbor, Mich., on Sept. 12, 1898, Cooley lectured on the commission to Michigan law students.

Besides fulfilling his teaching, administrative and judicial obligations, Cooley wrote extensively. His works included state supreme court opinions; periodical articles; editions of Blackstone's (1871) and Story's (1873) *Commentaries*; and treatises on *Constitutional Limitations* (1868), *The Law of Taxation* (1876), *Law of Torts* (1879) and *Constitutional Law* (1880). (E. G. BN.)

**COOLIDGE, (JOHN) CALVIN** (1872-1933), 30th president of the United States, was born at Plymouth, Vt., on July 4, 1872. He came from a long line of frugal, modest and unpretentious New England farmers and storekeepers. His father had held a number of local elective positions and provided Calvin with an example of shrewd and practical political activity. The son faithfully mirrored his background.

After being educated in local schools, he graduated from Amherst college in 1895, studied law the following year and entered law practice at Northampton, Mass., in 1897. For Coolidge, law was the means for entering a succession of political posts. From his election in 1899 as a councilman of Northampton he moved up the ladder from one public office to another. He served as city solicitor, clerk of the courts, member of the general court (legislature) of Massachusetts, mayor of Northampton, state senator and lieutenant governor for three terms, beginning in 1916. Along the way Coolidge established himself as a rising politician, entrenched himself in the state Republican party and acquired the respect of the voters.

Coolidge's success in politics was the result of skilful bargaining ability in the political game. Plain in appearance and habits, he gained the allegiance of voters with his faithfulness to duty, honesty, discretion and practical common sense. A characteristic statement was: "Let men in public office substitute the light that comes from the midnight oil for the limelight." Coolidge's faith and principles, drawn from his Yankee origins and attractive to the nation after World War I, were fundamental and familiar. He held in high regard the law as a foundation for national stability; he gave national traditions deep respect; and he regarded the hard-working, moral individual as the basis of American civilization.

**Governor.**—Elected governor of Massachusetts in 1918, Coolidge began his administration capably and with moderation. He introduced economies by working for the elimination of offices and was the first governor of the state to submit an executive budget. Suddenly, in Sept. 1919, as a result of his actions in connection with the Boston police strike, Coolidge became a national figure. Boston's policemen, in defiance of the police commissioner, had organized a labour union that sought affiliation with the American Federation of Labor. They also requested recognition for their union from Massachusetts authorities and asked for improved conditions in the police force. Receiving no satisfaction, the police went on strike, walking off their posts late in the day, Sept. 9, 1919. In Boston the suspension of law enforcement resulted in disorder and riots for two nights and a day, despite the efforts of volunteer policemen and the Boston forces of the state guard, which had been called up by the mayor. Not until the opportune moment to move with greatest effect did Governor Coolidge order the entire state guard to duty in Boston to restore law enforcement and to demonstrate the principle that public servants must not desert their posts. Upon refusal of police authorities to reinstate policemen who had struck, Samuel Gompers, president of the American Federation of Labor, appealed to Governor Coolidge on behalf of the policemen. The governor replied publicly: "There is no right to strike against the public safety by anybody, anywhere, any time." In a tense nation beset by labour problems and fearful of civil disorder through repetition of events such as the Boston police strike, the Seattle general strike and the steel strike, Coolidge's words and actions received nationwide approval and acclaim.

**Vice-President.**—Soon after the Boston episode Coolidge was

re-elected governor by a large majority and his name was frequently mentioned as a possible Republican nominee for president in 1920. At the Republican national convention Coolidge was among a number of minor candidates for the presidential nomination, but a prolonged contest ended with the selection of Warren G. Harding. Coolidge was easily nominated for vice-president on the first ballot. In Nov. 1920 Harding and Coolidge won the election with 404 electoral votes to 127 for the Democratic candidates.

As vice-president, Coolidge broke precedent by attending President Harding's cabinet meetings, but otherwise he performed his duties with little public notice. He faithfully supported the administration's policies but was not involved with Harding's circle of friends and advisers. On Aug. 3, 1923, upon the death of Harding, Coolidge succeeded to the office of president. He broke precedent again by taking the oath of office from his father, a notary public, at Plymouth, Vt., where the vice-president was visiting.

**President.**—When President Coolidge came to office he inherited from Harding a divided party, a fractious congress, a national administration discredited by scandals, and pressing problems of domestic and foreign policy. Cautiously, quietly and with skill Coolidge brought about a reformation in the administration and gained control of his party so that when the Republicans met in national convention in June 1924, his nomination for president proceeded smoothly. By minimizing problems and pointing with pride to traditional institutions for security and faith, President Coolidge became a fondly accepted symbol of calm, practical, common-sense leadership. Coolidge's speeches on economy, better local government, the need of the spiritual element in politics, obedience to law and religious toleration were accepted as covering the principal problems facing the nation at that time. Aiding Coolidge in the public view was his charming wife, Grace Goodhue Coolidge, and public sympathy was freely given to both upon the death of their younger son on July 7, 1924. As president, Coolidge was restrained and avoided issues whenever possible. He left many matters to his cabinet officers and relied upon such advisers as Secretary of the Treasury Andrew Mellon and Secretary of Commerce Herbert Hoover for initiative in the development of positive policies.

In the 1924 election campaign the Democratic party was torn by dissensions. The independent Progressive candidacy of Sen. Robert M. La Follette was not widely popular, but it enabled Republican campaigners to speak of "Coolidge or Chaos" and to call upon the voters to "Keep Cool With Coolidge." Such negative factors and the absence of appealing issues combined with business prosperity to give Coolidge 15,700,000 popular votes and 382 electoral votes to 8,400,000 popular votes and 136 electoral votes for John W. Davis, the Democratic candidate. The Progressive candidate, Senator La Follette, polled 4,800,000 popular votes and 13 electoral votes.

Coolidge's administration was distinguished by absence of crises, lack of spectacular political leadership and the expansion of prosperity. An outstanding Coolidge policy was noninterference by government in the affairs of business and industry. Regulatory agencies became institutions for the assistance of business; a program of tax reductions favoured capital, and a high protective tariff was maintained. Coolidge was particularly attached to government efficiency and economy as means for reducing tax burdens, declaring, "Economy is idealism in its most practical form." The president's policies of limited government participation in economic affairs and of governmental economy put him firmly in opposition to effective farm relief proposals and the payment of a bonus to World War I veterans. Congress passed the bonus over his veto in 1924, but he was able to stop the McNary-Haugen farm relief bill by vetoes in 1927 and 1928. To Coolidge the deep-seated farm problem was a passing thing that would cure itself in time without substantial government assistance.

President Coolidge reflected general public sentiment by pursuing a foreign policy of aloofness. His administration was not extremely isolationist: it wished to assist in the furthering of good

relations, peace and disarmament, but without entanglements. Coolidge unsuccessfully urged U.S. adherence to the World court but wished the nation to remain free of the League of Nations; he favoured naval disarmament as a step toward peace and as an economy measure but maintained that the war debts should be repaid to the United States. The "Good Neighbour" policy toward Latin America was forecast when Coolidge appointed Dwight Morrow to be ambassador to Mexico. The most notable event in the administration's foreign relations was the negotiation in 1927 of the Kellogg-Briand pact to outlaw war. Coolidge's negative policies of detached economic nationalism and noninvolvement in economic trends meant the postponement of problems. This, together with his complacent encouragement of the speculative boom in the stock market, produced predicaments for future administrations.

Toward the end of his administration, Coolidge issued on Aug. 2, 1927, the statement: "I do not choose to run for president in 1928." The full meaning of this cryptic declaration then and later aroused speculation. As a result, the way was cleared for Herbert Hoover to move forward as the principal candidate for the Republican presidential nomination in 1928. President Coolidge stepped down from his office, being succeeded by Hoover, on March 4, 1929.

CALVIN COOLIDGE

Coolidge thereupon entered a brief period of retirement during which he wrote his autobiography and contributed occasional articles to newspapers and magazines. He died on Jan. 5, 1933, at Northampton, Mass. See also UNITED STATES (OF AMERICA): History.

**BIBLIOGRAPHY.**—Calvin Coolidge, *The Autobiography of Calvin Coolidge* (1929), *The Price of Freedom: Speeches and Addresses* (1924); Claude M. Fuess, *Calvin Coolidge, The Man From Vermont* (1940); William Allen White, *A Puritan in Babylon: the Story of Calvin Coolidge* (1938). (J. H. SE.)

**COOLIDGE, WILLIAM AUGUSTUS BREVOORT** (1850–1926), pioneer alpinist and authority on alpine geography and history, was born on Aug. 28, 1850, near New York city, and educated at St. Paul's school, Concord, N.H.; Elizabeth college, Guernsey; and Exeter college, Oxford. From 1880 to 1881 he was professor of English history at St. David's college, Lampeter, and until 1885 he was modern history tutor at Magdalen college, Oxford, where he was elected a fellow. He was ordained in 1882 and acted for 12 years as honorary curate at South Hinksey, Oxford. He was introduced to the Alps in youth by his aunt, and climbing and the study of the Alps became the main interest of his life; in 1896 he went to Switzerland and settled at Grindelwald. His chief ascents were made between 1865 (Col du Géant) and 1898 (Ortler), and he made the first winter ascent of the Wetterhorn and Jungfrau (1874) and the Schreckhorn (1879). His guide was the famous Christian Almer and later Almer's son. Coolidge made more than 1,700 expeditions in the French, Swiss and Italian Alps. His most notable books are *Swiss Travel and Swiss Guidebooks* (1889), *Josias Simler et les origines de l'alpinisme jusqu'en 1600* (1904) and *The Alps in Nature and History* (1908). He edited the first volume of the revised edition of J. Ball's *Alpine Guide* (1898), and two issues of Murray's *Handbook to Switzerland*, 19th ed. (1904). He was the sole author of several volumes in the *Climbers' Guide* series. He died at Grindelwald on May 8, 1926. (D. MN.)

**COOLING SYSTEMS.** Many machines and industrial processes require cooling systems for proper functioning. The automobile engine is a familiar example. The cylinders of all internal-combustion engines (*q.v.*) require cooling because of the inability of the engine to convert all of the energy released by combustion into useful work. A typical automobile cooling sys-

tem is illustrated below. The coolant is delivered by the pump to the front of the cylinder block and is directed along the row of cylinders by the distributor tube. Flow is then upward to the cylinder head and forward to the thermostat which opens for flow to the radiator at the design jacket temperature, 160° to 180° F. The bypass maintains circulation and equalizes temperatures within the cylinder block when the thermostat is closed. The cooling system is usually pressurized to raise the boiling point of the coolant so that a higher outlet temperature can be maintained to improve thermal efficiency and increase the heat-transfer capacity of the radiator. A pressure cap on the radiator maintains this pressure by valves that open outwardly at the design pressure and inwardly to prevent a vacuum as the system cools.

Some engines, particularly aviation engines and small units for lawn mowers, chain saws, etc., are air cooled directly. Air cooling is accomplished by forming thin metal fins on the exterior surfaces of the cylinders to increase the rate of heat transfer by exposing more metal surface to the cooling air. Air is forced to flow rapidly through the spaces between the fins by fans or blowers. Airplane engines are especially well adapted to air cooling because the propeller air stream provides ample cooling air without any power consumption. Few motor vehicles have used air cooling, principally because the temperature cannot be closely regulated as it is when water cooled.

Condensation of vapours by cooling is necessary for equipment operating on closed cycles, such as refrigerating systems and steam-turbine plants. The condenser (*q.v.*) is a heat exchanger (*q.v.*), with one path provided for the circulation of the ammonia vapour or steam to be condensed and a second path for the cooling water. Large-capacity cooling systems are necessary to recool water for the condenser.

Spray ponds are sometimes employed with nozzles that discharge the water upward. Cooling towers are more efficient, require less space and conserve water. The cooling tower is erected over a concrete basin with a ventilated casing and a redwood framework. Inlet louvers admit air at the lower portion of the structure and induced-draft fans discharge it at the top. The water to be cooled is distributed near the top of the tower to a system of spray nozzles uniformly disposed over the area. The water descends through wooden fill racks that retard the falling drops and increase the surface in contact with air. The water is cooled as it descends to the catch basin both by heat transfer to the air and by evaporation of some of the water. A pound of water, in

BY COURTESY OF CHRYSLER CORP.

CUT-AWAY VIEW OF AUTOMOBILE COOLING SYSTEM

evaporating, acquires its latent heat of evaporation of nearly 1,000 B.T.U. from the surrounding air and water droplets. One pound of water evaporated in this manner will reduce the temperature of 100 other pounds of water by nearly 10°.

Closed systems are used when the water to be cooled is expensively treated feed water. A heat exchanger is then located in the base of the cooling tower with the treated water circulated through it and cooled by raw water flowing over its surface. The raw water is then pumped to the top of the tower and recirculated.

Electrical equipment requires cooling, principally to prevent damage to the insulating material. Large transformers are surrounded by insulating oil that circulates by thermosiphon action

through vertical tubes extending from top to bottom outside the housing. Forced circulation of the oil and cooling air is sometimes necessary. Large electrical generators are cooled by air that has passed through heat exchangers and is recirculated by blowers in a closed system.

Large metal-processing shops have cooling systems that circulate a coolant composed of water and soluble cutting oil to be flowed over the metal-cutting tools. Dies for the extrusion of wire and other metal shapes require cooling, as do the rolls in steel mills.

See also AIR CONDITIONING; HEATING AND VENTILATION.

(O. C. C.)

**COOMB** (COOMBE, COMBE), a term frequently used in southwestern and southern England for a short, closed-in valley, either inland on the side of a down or forming a small coastal feature. The etymology of the word is uncertain. It appears in place names; e.g., Ilfracombe, Temple Combe, Combe Martin. The Welsh *cwm* means "hollow" or "valley" and may be compared with *cwm* in several Cumbrian and Scots place names.

Coombs occurring in the chalk lands of southeastern England are usually waterless and partly filled with a rubble of angular chalk fragments. This is known as coomb rock and is believed to have originated as a glacial sludge during the later phases of the Ice Age.

(L. D. S.)

**COONCAN** is an adaptation of the old Spanish game of *conquian*—derived from the Spanish words *con* "with" and *quien* "whom." The game was taken by the Spaniards to Mexico, from where it spread to the southwestern United States. It also invaded England, where it is still played; in the United States it has been almost entirely supplanted by its offspring *rummy*.

As in all rummy games, the object in cooncan is to get rid of one's hand by forming it into sets of three or more cards of the same rank or of the same suit in sequence. Two full 52-card packs are used, plus 2 jokers, which are wild and therefore may be named to represent any card to complete a set. Local rules differ as to whether a completed set may or may not be melded; i.e., placed face up on the table. When a set is melded, other players may add cards to it. In some variations cards left in players' hands are scored, a popular scale being: jokers 15 each, aces 11, face cards 10 and other cards their number, or index value. The game can be played by any number of players up to seven. It is best for four or five. See also *RUMMY*. (G. Mh.)

**COOPER, ALEXANDER** (before 1609–1660), English miniaturist, elder brother of Samuel Cooper (q.v.), was probably born in London. He died in Stockholm at the beginning of 1660, having spent the greater part of his life out of England. He was a pupil of his uncle John Hoskins and perhaps of Peter Oliver. Cooper was in Holland by 1631 or 1632, where he painted a series of miniatures (now in Berlin) of the king and queen of Bohemia and their seven children. During 1644–46 he was at The Hague and in 1647 went to Stockholm, where he worked for Queen Christina and her successor, Charles X. He seems to have been in Copenhagen in 1656. There are two miniatures by Cooper in the Victoria and Albert museum, London, and one in Stockholm.

See B. S. Long, *British Miniaturists* (1929); G. Reynolds, *English Portrait Miniatures* (1952).

(P. J. Mv.)

**COOPER, SIR ASTLEY PASTON** (1768–1841), English surgeon, whose operation (1827) of tying the abdominal aorta for aneurism is historic, was born at Brooke, Norfolk, on Aug. 23, 1768, the son of a clergyman. He studied under Henry Cline, surgeon at St. Thomas' hospital, London, and attended the lectures of John Hunter. He was connected with St. Thomas' as demonstrator in anatomy (1789–91), joint lecturer with Cline on anatomy and surgery (1791–1800), and then went to Guy's hospital as surgeon. In 1813 he became professor of comparative anatomy to the Royal College of Surgeons, of which body he was president in 1827 and 1836. Cooper was vice-president of the Royal society in 1830 and received a baronetcy in 1820. He died in London on Feb. 12, 1841.

The greatness of Cooper's achievement in tying the abdominal aorta can be appreciated only when it is borne in mind that the operation was accomplished before the days of antiseptic surgery.

In the first volume of the *Transactions* of the Medico-Chirurgical society, of which he was one of the founders, he published (1803) an account of an attempt to tie the carotid artery. Of his numerous works the most important is *The Anatomy and Surgical Treatment of Hernia*.

See *Life of Sir Astley Cooper*, by his son, B. B. Cooper (1843).

**COOPER, GARY** (FRANK JAMES COOPER) (1901–1961), U.S. motion-picture actor whose portrayal of homespun characters established him as a glamorized image of the average man, was born in Helena, Mont., May 7, 1901. His father, Charles Henry Cooper, who had emigrated from England to Montana as a young man and married a British-born Montana girl, was a successful lawyer.

On a ranch owned by his father, Frank Cooper acquired the practical experience that later made it possible for him to get cowboy parts in Hollywood westerns—but impossible, he commented, to take them seriously.

In 1924 he dropped his enrollment at Grinnell college, Ia., went to Hollywood and earned a precarious living as a cowboy "extra." He advanced to leading parts in low-budget westerns and was rechristened Gary Cooper by his agent. Brief appearances in the pictures *It* (1927) and *Wings* (1929), in both of which Clara Bow was the feminine lead, led to his being selected to star with her in *Children of Divorce*. A far more characteristic role, however, was that of the unsophisticated small-town man fighting for his concept of integrity in *Mr. Deeds Goes to Town* (1936). Working on his 88th picture in London in 1960, he confessed to being a tired man, but added: "The urge to act stays with you."

He died at Los Angeles, Calif., May 13, 1961.

(J. Av.)

**COOPER, JAMES FENIMORE** (1789–1851), the first major U.S. novelist, best known as the author of the Leatherstocking tales, was born at Burlington, N.J., Sept. 15, 1789. When he was a year old, the family moved to Cooperstown, N.Y., a frontier village founded by his father. There Cooper lived as a boy in the lake region of New York state. He grew up as a youth of wealth and position, whose father was one of the large landowners of the state. (His father was also a notable figure in New York politics, a staunch Federalist, and a Quaker so belligerent that he lost his place in the Society of Friends.)

Cooper entered Yale college at the age of 13, the youngest member of his class. Of his college career little is known, except that he was the best Latin student of his class, and that he was expelled in his junior year for some prank—there is a story of his exploding a charge of gunpowder in the lock of a tutor's door. In 1806 he sailed as an apprentice seaman to England, and in 1808 became a midshipman in the U.S. navy. His father was killed in 1809 by a political opponent. In 1811 he married Susan De Lancey, daughter of a Tory family; he resigned from the navy and settled down to the life of a country gentleman.

"I could write you a better book than that myself," Cooper is supposed to have said to his wife, concerning a current English novel. Then rising to her inevitable challenge, he wrote his first work of fiction, *Precaution* (1820), a poor novel. Having thus begun writing at the age of 30, Cooper went on to produce 50 separate works during the remaining 32 years of his life. Thirty-one of his works are novels. He became famous with his second novel, *The Spy* (1821); in this story of the American Revolution "the Cooper hero" appears for the first time, the unsung spy of democracy, Harvey Birch. The book was immensely popular in many countries, in a period of rising democratic nationalism. With *The Pioneers* (1823), Cooper entered upon the Leatherstocking tales, and in the same year produced *The Pilot*, the first sea story of its kind.

In 1826, at the height of his fame, he went abroad, remaining in Europe for seven years. Writing rapidly, he moved from a strongly American subject matter and attitude (*The Last of the Mohicans*, 1826; *The Prairie*, 1827) to a treatment of men and manners in European settings. He now wrote travel books and social criticism as well as fiction. In 1833 he returned to the U.S. and moved back to Cooperstown where he lived during the rest of his life. He wrote still other kinds of books, including a history of the U.S. navy (1838). Of his later novels, a few of the best are

*Afloat and Ashore* (1844), *The Wing-and-Wing* (1842), *Satanstoe* (1845), the best of a trilogy on New York state antirentism and the later Leatherstocking tales.

Cooper's great work was the Leatherstocking tales, which form an authentic American "myth," if by that term we mean a story which has appealed to readers at every level of sophistication from its own day to ours, which is known world over, and which has placed its hero, the Leatherstocking, very near the head of any list of American heroes of fiction. The five novels of the series were not published in their narrative order, but can best be mentioned in that sequence. The tales open with *The Deerslayer* (1841), in which Natty Bumppo appears at the age of 20, in the year 1740, on his first warpath. In *The Last of the Mohicans* (1826) he is known as Hawkeye, and appears at the height of his powers in Cooper's most rapid-fire story of flight, pursuit and capture. As the Pathfinder in the novel of that name (1840) he takes part in the French and Indian wars on Lake Erie, the "inland sea," in a novel which is both sea story and frontier story. *The Pioneers* (1823), the first written of the series but the fourth in narrative order, depicts Bumppo and his Indian companion Chingachgook as old men, at the low ebb of their fortunes, living in a frontier village. In this story Chingachgook dies. As "the old trapper," the hero makes his last appearance in *The Prairie* (1827), of which the setting is the Great Plains in 1804. He dies in this story, in exile and honour among the Pawnee Indians of the west. The tales make up an epic of heroic action occurring through 60 years of time, over the space of half a continent. Cooper's epic intention was explicit; he sought to achieve "the elevation of romance," by which he meant the level of prose epic. The most interesting of the novels to a modern reader might be *The Pioneers*, a realistic picture of life in a frontier town; or *The Deerslayer*, which was in D. H. Lawrence's eyes "a lovely myth"; or *The Pathfinder*, which Cooper himself most liked for its intricate plot and action.

Cooper's characteristics as a novelist are those of an energetic and impatient craftsman. The best of his novels are marked by both grandeur of conception and carelessness of detail. His style is uneven, and was even in its own day a somewhat old-fashioned instrument patterned after 18th-century models. His characters are simple, strong, and strongly contrasted, and are not rendered in what the modern reader may think of as psychological detail. Both Cooper's Indians and his women have been harshly criticized. His women are in fact genteel, dimly seen, and often incidental to the story—in at least one novel he inadvertently changed his heroine's name halfway through the narrative. His Indians are a different matter; though Cooper has been described as a portrayer of "the noble Red Man" only, his many Indian characters do in fact range from heroic to ignoble and are of many sorts. That he depicted "mere savages" as heroic at all was offensive to some "realists" in his own time and later. Cooper's plots are loose and often extravagant, rising to power in scenes of pursuit and combat; he tended to think of his stories as sequences of such "pictures" of violence. Coincidence looms large in some of his stories. It is for a few central heroic characters that Cooper is most admired: the Leatherstocking and his friend Chingachgook, the Great Serpent; Long Tom Coffin (of *The Pilot*); Harvey Birch, the spy. Finally, Cooper's novels are, to a greater extent than is often realized, founded on intellectual premises and moral convictions: his characters embody values, his plots are dramas of intellectual and moral conflict, and his aim is often (in his words) "the delineation of principle."

American scholars have also discovered in Cooper a significant social critic. In *The American Democrat* (1838) and other non-fiction works, as well as in the novels *Homeward Bound* and *Home as Found* (also 1838) Cooper both defended and criticized American democracy. In the age of Jacksonian "leveling," he was concerned to maintain a difficult position: that a political democracy, in which he wholeheartedly believed, should yet preserve the best of such traditional values as good taste, intellectual and artistic standards, and the moral excellences embodied in the concept "gentleman." Arguing for his ideal of a democratic gentleman, he was attacked by both social conservatives and political radicals

as an "aristocrat" and worse. He was also subjected to such personal abuse and calumny in the press that he brought libel suits against his attackers, winning most of them and doing much, in the process, toward the establishment of effective libel laws in the American courts. In Cooper's fiction there is also social criticism; an interesting example is *The Bravo* (1833), a novel about a dictatorship of an élite, which has strong relevance to problems of the 20th century.

Cooper's fame in his own day was great, and continued high through the 19th century. Mark Twain struck his reputation its severest blow with his essay, "Fenimore Cooper's Literary Offenses" (1895), in which he assailed his predecessor for breaking "eighteen" of the "nineteen rules governing literary art." Mark Twain attacked particularly Cooper's style, which is indeed the opposite of his own, being complex and Latin derived rather than simple and Anglo-Saxon.

Cooper was a careless stylist in his narratives of action, but in his more thoughtful writings used his terms with some precision—"agreeably to Johnson," as he put it. Mark Twain's opinion, which became the conventional view of Cooper early in the 20th century, can perhaps be balanced by the opinions of other novelists: Balzac admired him greatly, taking his fiction as a model for his own first serious novel (*Les Chouans*), which reads like a *Last of the Mohicans* set in Brittany. Victor Hugo rated him higher than Sir Walter Scott. To Joseph Conrad he was "a rare artist . . . one of my masters." Other novelists from Herman Melville to D. H. Lawrence have admired him as "the American novelist."

Of Cooper's sources and development as a novelist, a few observations may suffice. His first novel reads like a poor imitation of Jane Austen, and the Austen novel of manners may well have influenced Cooper's later interest in the social novel. But Scott was his elder contemporary, and as time went on his chief rival in the historical romance. Cooper's negative aim was to avoid the extravagances of the "sentimental" and "Gothic" schools of fiction. Cooper's early novels are his most realistic in detail, and show more of what he called his "native fire" than his late works; his late fiction presents idealized characters, scenes and action.

Cooper's place in literary history is secure on two counts—as the first U.S. professional man of letters, and as a literary innovator. Both the sea romance and the frontier adventure story of flight and pursuit are kinds of fiction which he invented. He is one of a very few American authors who have had literally a world audience from his own day to the present.

Lounsbury, *Fenimore Cooper* (1882); James Grossman, *James Fenimore Cooper* (1949). For a critical analysis, see Arvid Shulenberg, *Cooper's Theory of Fiction* (1955). (Ad. Sr.)

**COOPER, JOHN MONTGOMERY** (1881–1949), U.S. anthropologist and Roman Catholic priest, who specialized in the ethnology of South America, was born Oct. 28, 1881, in Rockville, Md. He received his Ph.D. (1902) and S.T.D. (Doctor of Sacred Theology, 1905) at the American college in Rome. In 1923 he began teaching anthropology at the Catholic university, in Washington, D.C.; in 1935 he became head of the department of anthropology—the first such department in a U.S. Catholic institution. His field work was done among the Naskapi, Cree and other Algonkian tribes of northern Canada, and among the Gros Ventre of Montana. Although he never traveled to South America, he became an authority on the region. His first ethnological work, *An Analytical and Critical Bibliography of Tierra del Fuego* (1917), marked his lifelong interest in the "marginal peoples" of southern South America, northern North America and other regions, whom he saw as having been pushed back into less desirable territories by later migrations, and as representing cultural survivals from the past. This thesis was presented in his *Temporal Sequence and the Marginal Cultures* (1941). Cooper was president of the American Anthropological association (1940) and founder and editor of the quarterly *Primitive Man*, to which he frequently contributed. He died on May 22, 1949, in Washington, D.C.

Cooper's other works include articles in vols. 1, 2 and 5 of the *Handbook of South American Indians*, Bureau of American Ethnol-

ogy *Bulletin* 143 (1946-50), Julian Steward, ed.; and *The Gros Ventres of Montana* (1957).

See also R. Flannery, "John Montgomery Cooper, 1881-1949" with a complete anthropological bibliography by J. Stine, in *American Anthropologist*, vol. 52 (January-March 1950). (R. Fr.)

**COOPER, PETER** (1791-1883), U.S. manufacturer, inventor and philanthropist, probably best known as the founder of the Cooper union (q.v.), was born in New York city on Feb. 12, 1791. He entered into various industrial activities early in life and in about 1828 built the Canton ironworks in Baltimore, Md., the foundation of his great fortune. In 1830 Cooper designed and constructed the first steam locomotive built in the U.S., "Tom Thumb," which was about the size of a modern handcar. Cooper's other notable accomplishments in the industrial world included first construction of iron structural beams (1854), first U.S. use of the Bessemer process (1856), and construction of the largest blast furnace in the country at that time. Actively interested with Cyrus Field in the Atlantic cable, Cooper was president of the New York, Newfoundland and London Telegraph company and the North American Telegraph company. He took a prominent part in educational affairs and conducted the campaign of the Free School society to its successful issue in 1842, when a New York state law was passed forbidding the support from public funds of any "religious sectarian doctrine." Previously a hard-money Democrat, Cooper joined the Greenback party after the Civil War and in 1876 was its presidential candidate. He died in New York city on April 4, 1883. He published *The Political and Financial Opinions of Peter Cooper, With an Autobiography of His Early Life* (1877) and *Ideas for a Science of Good Government, in Addresses, Letters and Articles on a Strictly National Currency, Tariff and Civil Service* (1883). (W. H. D.)

**COOPER, SAMUEL** (1609-1672), English miniaturist, was perhaps the most celebrated of all English artists in his own day, enjoying a European reputation as a portraitist. He was the younger brother of Alexander Cooper (q.v.) and, like him, a pupil of their uncle, John Hoskins. Cooper worked for Oliver Cromwell, making the most celebrated likeness of the lord protector, and also for the restored monarchy and court and is mentioned several times in the diaries of both John Evelyn and Samuel Pepys. The latter paid £30 for a miniature of Mrs. Pepys. Cooper, who may have been of Dutch refugee descent, was widely traveled and an excellent linguist. He died in London on May 5, 1672. There are examples of his work in the British royal collection, in the Victoria and Albert museum, London, and at Oxford and Cambridge.

See B. S. Long, *British Miniaturists* (1929); G. Reynolds, *English Portrait Miniatures* (1952). (P. J. Mx.)

**COOPER (COUPER), THOMAS** (c. 1517-1594), English bishop and author of a famous dictionary, was born in Oxford, where he was educated. He became master of Magdalen College school, and afterward practised as a physician in Oxford. In 1565 appeared the first edition of his most notable work, *Thesaurus Linguae Romanae et Britannicae*. Three other editions followed: 1573, 1578 and 1584.

Queen Elizabeth I was greatly pleased with the *Thesaurus*, which became known as *Cooper's Dictionary*. Cooper, who had been ordained about 1559, was made dean of Christ Church, Oxford, in 1567. Two years later he became dean of Gloucester, in 1571 bishop of Lincoln and in 1584 bishop of Winchester. Cooper defended the practice and precept of the Church of England against the Roman Catholics on the one hand and against the Martin Marprelate writings and the Puritans on the other. He died at Winchester, April 29, 1594.

**BIBLIOGRAPHY.**—Cooper's *An Admonition to the People of England* (1589) was reprinted in 1882 and his *Answer in Defence of the Truth Against the Apology of Private Mass* (1562) in 1850.

**COOPER, THOMAS** (1759-1839), U.S. educator, chemist, expert on jurisprudence and political philosopher described by John Adams as "a learned, ingenious, scientific, and talented madcap." was born in London, Oct. 22, 1759, and studied at Oxford. He emigrated to the United States about 1793 and began the practice of law, becoming president-judge of the 4th district of Pennsyl-

vania in 1806. Thomas Jefferson secured for him the appointment as first professor of natural science and law in the University of Virginia, a position that Cooper was forced to resign under the fierce attack made upon him by the Virginia clergy. In 1819 he went to South Carolina college, Columbia, where he taught chemistry and political economy, and in 1821 became president of the college. He resigned his presidency in 1833 and, in the following year, his professorship, because of the opposition within the state to his liberal religious views. A born agitator, he constantly preached the doctrine of free trade and tried to show that the protective system was especially burdensome to the south. His remedy was state action against the tyrannical acts of the federal government, and he exercised considerable influence in preparing the people of South Carolina for nullification and secession. Cooper died in Columbia on May 11, 1839. As a philosopher he was a physiological materialist and a severe critic of Scottish metaphysics.

Among his publications in various fields were *Some Information Respecting America* (1794); *Political Essays* (1800); *Lectures on the Elements of Political Economy* (1826); *A Treatise on the Law of Libel and the Liberty of the Press* (1830); *Statutes at Large of South Carolina*, 5 vol. (1836-39); *Introductory Lecture on chemistry* (1812); and a translation of Broussais' *On Irritation and Insanity* (1831), with which were printed several of his own essays.

**COOPER, THOMAS** (1805-1892), English Chartist and writer whose political epic, *The Purgatory of Suicides*, versified the Chartist principles for which he worked and suffered imprisonment, was born at Leicester, March 20, 1805. He had a passion for knowledge, and studied extensively while working as a shoemaker. In 1827 he became a schoolmaster and in 1829 a Methodist lay preacher, but he held few positions long. His conversion to Chartism (q.v.) led to his dismissal from the *Leicestershire Mercury* (1841), and he became editor of the *Midland Counties Illuminator* and other Chartist weeklies. He organized the Leicester hosiery knitters into an "army" to study Chartism and literature, and in 1842 toured the Potteries urging support of the general strike.

Convicted of sedition in 1843, he spent two years in Stafford jail, where he wrote his verse epic, in Spenserian stanzas, and a collection of tales, both published in 1845. After his release he became a lecturer, but he quarreled with the Chartist leader Fergus O'Connor and gradually his political enthusiasm declined. After 1856 most of his writings and lectures were in defense of Christianity. He died at Lincoln, July 15, 1892.

He also wrote *Poetical Works* (1877) and the *Life of Thomas Cooper, Written by Himself* (1872).

See R. J. Conklin, *Thomas Cooper, Chartist* (1936).

**COOPERAGE**, the trade of making barrels from staves and hoops. Wood is commonly used for the staves and steel for the hoops. In the packaging trade, cooperage refers to barrels themselves as well as the manufacture of them. Cooperage is of great antiquity; Pliny ascribes its invention to the inhabitants of the Alpine valleys.

There are two types of cooperage, slack and tight. Slack barrels are made to hold dry products; they can be made of soft woods and do not require precise workmanship. Tight barrels are made to hold liquids and must be constructed very carefully of high-grade woods. Another difference is that the tight barrel has a bung-hole for filling and emptying; the slack barrel does not.

Slack barrels usually are made of pine, although hardwoods are used for some relatively high-value products. Tight barrels are usually made from white oak. The highest grades of sap-free white oak that are quarter-sawed with the grain from straight-grain timber are used for making whisky barrels. Tight barrels also may be made of red oak, gum, ash and Douglas fir. The type of wood that is used depends to a large extent on the material that will be packaged in the barrel. In any case, the wood must not produce undesirable characteristics, such as odours, in the product.

Tight barrels are frequently lined or sized. Lining consists of

coating the interior of the barrel with such materials as glue, sodium silicate or paraffin. Slack barrels are sometimes lined with paper or plastic bags to make them suitable for packaging dusty products.

Some automatic operations are used in most barrel plants and many are used in the manufacture of whisky barrels. Only a few barrels were made by hand in the early 1960s. In a typical operation, the wood for staves and headings is air-dried for at least a year and is then kiln-dried for 10–20 days to reduce the moisture content to 10%–12%. The wood is then cut and planed to the proper size and finish. A most crucial operation is the jointing of the edges of the staves and giving them the proper bilge (middle bulge) and taper so that when the barrel is completed the joints will be tight and the circumference of the bilge uniform.

The most complex part of the operation is "raising" the barrel. Staves are set vertically into a head truss ring, and a temporary hoop is placed over the other end. In this arrangement, the staves are passed through a steam tunnel to soften them; while soft, they are drawn into their final shape and dried again. Whisky barrels are charred at this point to increase their ability to develop flavour in whisky while it is being aged. The barrel is then automatically conveyed to a crozer, a machine that trims the ends of the staves and cuts the croze, the groove near the end of the stave into which the head pieces will be fitted. The temporary end rings are pulled off, the head pieces fitted and the permanent head hoops put in place. Head pieces usually are made of two or more pieces jointed by wooden dowel pins. Finally, the temporary bilge hoops are removed and the rest of the permanent hoops, usually a quarter hoop and a bilge hoop on each end, are driven into place. The bung-hole is bored and the barrel is tested for leaks with water under pressure. Both slack and tight barrels are shipped with the heads in place. Tight barrels are, of course, filled through the bung-hole, but the heads must be removed from slack barrels for filling. Barrels are generally made near their point of use to avoid the expense of shipping empty barrels long distances.

Barrels are durable and relatively easy to handle because of their shape. However, they are heavy, are difficult to open without destroying the head pieces and are relatively expensive because of the time and labour required to make them. As a result, the use of wooden barrels declined substantially after World War II.

By far the major use for wooden barrels in the U.S. in the early 1960s was for aging whisky. When barrels are used for this purpose they may be used only once, according to U.S. law. Some tight wooden barrels are still used for shipping animal and vegetable oils and liquid chemical products, but they have been largely superseded by metal drums and by bulk tank transportation on special railroad cars and truck trailers. Slack barrels have been used in the past for packaging cement, dry chemical products, china, fresh and dried fruit, fish and numerous other products; this type of barrel has suffered from competition principally from multi-wall paper shipping sacks and corrugated paperboard cartons, which are not as durable as wood barrels but cost considerably less. Fibre drums made from multiple layers of paperboard, usually with a vapour barrier, also have competed effectively with wooden barrels. The outlook in the early 1960s regarding the future use of barrels was for a continuing decline except for the aging of whisky.

(P. B. BA.)

**CO-OPERATIVES.** Co-operative organizations founded for mutual economic aid exist in most countries of the world—in advanced as well as in underdeveloped countries and colonial possessions, and in urban as well as in rural areas. The co-operative way of doing business takes many forms, ranging from local to centralized and federated organizations, and from highly specialized to multipurpose societies.

Since earliest times people have worked together in large or small groups to attain social, religious, or economic objectives, but the modern co-operative movement is not much more than 100 years old. The underlying social philosophy was formulated during the first half of the 19th century by writers such as Robert Owen (q.v.) in Great Britain and Charles Fourier (q.v.) in France. The basic organizational structure can be said to date from 1844 with the establishment in England of the first successful con-

sumers' co-operative, the Rochdale Society of Equitable Pioneers. The society created a set of organizational and working rules, popularly known as the Rochdale principles, that have been adopted, with modifications, in most countries and used for a wide variety of co-operative activities. Briefly, these principles call for democratic control, open membership, no religious or political discrimination, service at cost and education of the members. Members have a dual relationship to their association. They contribute its capital and are also customers or patrons. In many countries governmental or co-operative banks aid in financing new and old associations. Credit societies developed in Germany between 1860 and 1875 under the leadership of F. H. Schulze-Delitzsch and F. W. Raiffeisen. Modern credit unions (q.v.) are patterned largely on the German experience. (For agricultural co-operation see AGRICULTURAL ECONOMICS: *Agricultural Co-operation.*) (J. M. TL.)

## GREAT BRITAIN

**Pre-Rochdale Co-operation.**—As noted above, the British co-operative movement had its origins in the Owenite movements of the early 19th century. There were many earlier instances of joint purchase, production and sale, but these never constituted or originated a movement. Owen regarded the formation of human character as being of prime importance, for the happiness of each would depend upon the characters of all. Under the existing system, he observed, bad characters were formed because avarice was encouraged. All were trained to seek pecuniary gain and the best feelings of human nature were sacrificed to the love of accumulation. Competition and the pursuit of profit resulted in the exploitation of labour, unemployment, increasing poverty, misery and crime. He advocated as a remedy the establishment of co-operative communities. None that he founded was successful but the idea had a powerful appeal and generated a movement: in 1821 George Mudie founded the Co-operative and Economical society and published *The Economist*, which propagated Owenite views. Both the society and the journal came to an end in 1823. The London Co-operative society (1824) then became the main propagandist body, issuing *The Co-operative Magazine* (1826–30) and concentrating upon the desirability of mutual aid and equal distribution. It carried co-operative ideas into such working-class organizations as branches of trade unions, friendly societies and mechanics' institutes.

A branch of the latter in Brighton, Sussex, attracted the attention of Dr. William King and aroused his interest. Under his guidance two co-operative organizations were founded in Brighton in 1827, one to raise a fund by small weekly subscriptions to enable members to join co-operative communities, the other to accumulate profits out of co-operative trading to finance the establishment of a co-operative community. Between 1828 and 1830 he published a monthly magazine *The Co-operator*, which had a wide circulation and was keenly studied by working-class Owenites, who regarded it as something of a textbook on co-operation. It explained how workers could develop co-operative communities through co-operative trading and production. According to the theory, a small amount of capital could be raised by subscriptions and a store opened, the management of which would provide the experience and knowledge to engage in larger ventures. If credit were neither given nor taken and speculative ventures avoided, little risk would be involved. Profits were not to be divided but were to accumulate in a capital fund to finance further co-operative enterprise, thereby enabling the co-operators to build their own houses, provide their own schools, educate their children on co-operative lines, acquire their own fields and workshops, employ themselves and evolve a community. The practice of co-operation during this evolution would educate the members in co-operative living: "the very act of co-operation would improve the character and change the nature of man . . . the greatest and most beneficial effects of co-operation will be upon the moral character . . . this is the final end and consummation of the cause." The formation of producers' societies was also advocated; trade unions were advised to invest their funds in co-operative enterprises and to start enterprises of their own. Advice on the con-

duct of co-operative business was given—credit must be avoided, there must be accurate bookkeeping and members must be educated in the art of co-operation and democratic administration.

A vigorous movement quickly developed. King claimed in 1830 that over 300 societies had been established as a result of his *Co-operator*. Co-operative congresses were held in the early 1830s and a co-operative wholesale company was established. Model rules were drawn up and approved which not only revealed the influence of King's *Co-operator*, but had a resemblance to some of the later rules of the Rochdale Pioneers. This movement, however, was almost extinct by 1835. Its collapse was bound up with the failure of Owen's National Equitable Labour exchange involved in the crash of the Grand National Consolidated Trades' union of 1834. This was a catastrophe for the co-operative movement, for it discredited Owen and Owenism with the working classes, but Owenism continued, although its national organization changed its name several times. Its activities were mainly propagandist and educational, still directed toward the establishment of communities. By 1840 there were 62 branches and it was claimed that 50,000 persons attended its lectures each Sunday. Their activities were carried on in buildings that were acquired in some towns and named Halls of Science or Social institutions.
